Here, we are primarily concerned with transfers between different generations of the same family, but we are interested also in how such payments are affected by public transfers. **Figure 1**, drawn from Cigno et al. (2006) shows the distribution, by age of the household head, of monetary help given to and received from noncoresident 'friends or relatives' by Italian households. It transpires from the graph that the probability of making a transfer is highest, and that of receiving one lowest, when the household head is in the 40–59 age range. Similar pictures can be constructed for other countries. What can be the reason for such a pattern? The economic explanations fall into two broad categories. One follows what is called the altruistic approach, whereby individuals are assumed to derive direct utility (satisfaction) from the well-being of other family members. The other assumes that individuals are ultimately self-interested. Transfers are straight, no-strings-attached gifts according to the first explanation, part of a strategy that is expected to bring direct or indirect benefits to the donor according to the second.

Altruistic Explanations

Simple altruistic explanations assume that sentiment is unidirectional: either from parents to children (*descending altruism*) or from children to parents (*ascending altruism*). More complicated versions allow for altruism in both directions.

Descending altruism underlies Richard Barro's and Gary Becker's theories of private transfers (Barro, 1974; Becker, 1974). This assumption allows them to model transfers within the family as the outcome of a single optimization, whereby parents decide how much each family member will consume subject to two constraints. The first of these constraints is that the present value of the consumption expenditures of all family members cannot exceed that of their incomes. The second is that the transfers received (the difference between consumption expenditure and income in any given period) by any family member other than the decision-maker(s) must be positive or zero, otherwise they would be rejected. Under standard conditions, the model predicts that transfers will not decrease (increase) as the income of the donor (beneficiary) increases. This is consistent with the observation (see **Figure 1**) that the probability of making a transfer is highest, and that of receiving one lowest, in middle life, when a person's earning capacity is at its peak. It is difficult to reconcile, however, with the observation that people continue to receive *inter vivos* transfers after the age of 60 (or even 75), when few of them will have living parents.

Descending altruism has an important policy implication. If it is assumed that parents make transfers to their children in the form of bequests, rather than *inter vivos*, the descending-altruism

Figure 1 Help given/received by age group.

model predicts that household saving is increased, dollar for dollar, by any current government deficit (Barro, 1974). That is because, conscious of the government intertemporal budget constraint, altruistic taxpayers will perceive any current deficit as a tax on their descendants (this is the so-called *Ricardian equivalence*, from the name of David Ricardo, who first detected it). As taxpayers will then respond to a current government deficit by saving more, in order to be able to leave their descendants bequests large enough to pay for the extra taxes, any net public transfer will be matched by private transfers of opposite sign. Ricardian equivalence does not hold exactly, however, if fertility is endogenous (i.e., if parents can choose how many children to have or, more realistically, condition the probability distribution of births through birth control) and parents derive satisfaction from the number of children, as well as from how much each of these children will consume (Becker and Barro, 1988).

One of the mechanisms that could generate a current government deficit is a pay-as-you-go public pension system, where current pensions are paid out of current contributions. Suppose that the government were to take a dollar off the social security contributions due by each of the present taxpayers, without any corresponding reduction in their pension entitlements. Each member of the next generation of taxpayers would then have to pay more in taxes. Knowing that, present taxpayers would then want to compensate their own children by making larger bequests to each of them. But this would make it more expensive to have an extra child than to raise the well-being of existing children. Under standard conditions, the present generation would then respond to the policy by having fewer children, and *more* than compensating each child for the heavier tax burden he or she will have to shoulder. Of course, the change in fertility behavior would result in a lower number of future taxpayers, and thus raise the burden on each of them. Given that the aggregate effects of a couple's actions are infinitesimal, however, the present generation will disregard them. Hence, the fertility rate will fall. Depending on whether the rise in transfers per child is proportionally larger or smaller than the reduction in the number of children, the saving rate could go either up or down.

By contrast, if the government were to promise higher benefits to current taxpayers already covered by old-age security, or extend coverage to new categories, and simultaneously raise taxes or contributions so as not to force a transfer in favor of present workers, there would be no effect on either saving or fertility. There is evidence (Cigno and Rosati, 1996 among others) that old-age security per se (i.e., in the absence of intergenerational spillovers) encourages household saving and discourages fertility, while deficits discourage saving. This empirical finding is consistent with the prediction of the Becker–Barro model that a deficit *could* result in lower savings, but contradicts that model's other prediction that, in the absence of intergenerational transfers, savings and fertility would remain the same.

The implications of ascending altruism are examined in Nishimura and Zhang (1992). Under this assumption, the direction of transfers is not from working-age parents to young children, but from working-age children to retirement-age parents. That is consistent with the observation that old people receive *inter vivos* transfers, but difficult to reconcile with the one that they also make such transfers. Given ascending altruism, however, parents view their children as an asset. If fertility is endogenous, working-age individuals (or couples) will then choose the composition of their portfolios so as to equate the marginal return to having children to that of holding conventional assets (capital). This carries the implication that any form of government generosity toward current taxpayers at the expense of future ones would induce the former to save more, not in order to leave larger bequests to their children as in the descending-altruism model, but in order to put some of the windfall aside for their own old age. By contrast, a fully funded expansion in pension coverage (a form of forced saving) would reduce voluntary saving. Both these predictions clash with the empirical finding, already mentioned, that deficits discourage voluntary household saving, while an increase in social security coverage per se encourage it.

Whichever its direction, unilateral altruism is thus an inadequate explanation of what we observe. Can bilateral altruism (parents love children, children love parents) do better? If family members were unanimous in their preferences, intrafamily transfers could again be described as the outcome of the maximization of a single preference function (this time common to all family members), subject only to the constraint that the sum of the discounted expenditures cannot be greater than the sum of the discounted incomes of all family members. There is now no restriction on the direction of money flows: depending on life-cycle patterns, transfers from middle-aged children to elderly parents may be positive in some families and negative in others. This is consistent with evidence of two-way flows between generations. But the model has also another behavioral implication: since the amount consumed by each family member depends on *total* family income, and not on his or her own individual income, changing the intrafamily distribution of income should not change the intrafamily distribution of consumption. This carries the strong policy implication that redistributive policies will be ineffective: taking a dollar off the rich (e.g., the parents) and giving it to the poor (e.g., the children) would reduce the amount voluntarily transferred from the former to the latter by exactly one dollar. Statistical tests based on this property (Cox, 1987; Altonji et al., 1992) reject the hypothesis.

Nonaltruistic Explanations

Nonaltruistic explanations are based on the assumption that individuals are interested only in their own lifetime consumption stream. If a person voluntarily surrenders money to a relative, it will be in return for something: either profit, or an improvement in the allocation of consumption (over the life cycle, or across states of the world). There does not seem to be any difference of substance between doing this and giving money to the grocer in exchange for a dozen eggs. Nonetheless, it is customary to classify as transfers any money or other assets changing hands within the family whenever there is no explicit *quid pro quo* (as there would be, for example, if a father paid his child to wash his car). If we want to find a nonaltruistic explanation for intrafamily transfers, we must then look for tacit agreements likely to bring benefits to all concerned.

In the presence of capital market imperfections, an opportunity for mutually advantageous arrangements among members of the same family stems from life-cycle income variations. Standard microeconomic theory predicts that individuals smooth consumption over the life cycle by borrowing from the market when they are young, and lending (buying assets) when they are middle-aged. In reality, however, minors cannot sign contracts, and young adults have difficulty in obtaining credit against future earnings. The very fact that people survive to adulthood in such circumstances is thus evidence that the young receive support from someone. But whom? Self-interested relatives, parents included, do not make presents. If the risk-adjusted return is at least as high as that offered by the formal capital market, they may make loans. There is an enforcement problem, however, in that elderly parents have no means of compelling a now middle-aged child to honor a promise made 20–30 years earlier (all the more so if there was only an implicit commitment, and no promise was actually uttered).

A possible solution is offered by Cigno (1993). Imagine a set of unwritten family rules, call it a 'family constitution,' prescribing the amount that a parent must pay a young child, and the amount that a grown-up child must pay an elderly parent, subject to the clause that nothing is due to a parent who disobeyed the rules. The clause makes paying one's own parents a condition for getting the same treatment from one's own children. A family constitution is self-enforcing if its rules are so designed that complying with them is at least as advantageous, for a person in middle life, as the alternative of having no children, giving nothing to parents, and providing for old age by buying capital. Evidence of the existence of self-enforcing family constitutions is reported in Cigno et al. (2006).

Mutual insurance arrangements ('I will help you if things go well for me and badly for you, you will help me if it is the other way round') are another possible source of intrafamily transfers. Here too, however, there is an enforcement problem. Why should anyone want to enter into such an informal arrangement if it is possible to buy insurance, perhaps even at a lower premium, from the market with all the safeguards afforded by the law? The insurance market has an advantage over the family in that individual risks are less likely to be correlated in a large heterogeneous population than in a small homogeneous group. On the other hand, however, informational (adverse selection and moral hazard) problems are less severe within the family because, compared with total strangers, family members have privileged information about one another's characteristics, and lower costs of monitoring one another's behavior. If the market does not offer insurance to certain individuals or for certain types of risk, or offers it only on very unfavorable terms, entering into some kind of intrafamily arrangement might then be the only or the cheapest way of getting insurance (Di Tella and MacCullogh, 2002).

If an intrafamily insurance agreement involves members of different generations, it will give rise to intergenerational transfers. An example is provided by the case where a family member, say a parent, transfers wealth or precommits to leave a bequest to a younger family member, say to a child, in exchange for a promise of indefinite old-age support (Kotlikoff and Spivak, 1981). Given that the duration of life is uncertain, such an arrangement will insure the parent against the risk of running out of money if he lives to a very old age. The problem is again enforcement, and the solution could again be a family constitution as in the case of intergenerational credit.

Let us now suppose that a family constitution is in place, and imagine that the government decides to raise pension entitlements. The present middle-aged will then want to shift less of their current spending capacity to old age than they would otherwise. Since the amount they are supposed to pay to their elderly parents under present family rules has not changed, however, some of them will find it advantageous to disobey the rules, and consequently give up the idea of receiving support from their own children in the future. They will then pay nothing to their own parents, have no children and possibly top up their expected pension benefits by buying conventional assets. Conversely, if the government were to cut current taxes or pension contributions without reducing pension entitlements, some middle-aged individuals, who would otherwise have found it advantageous to disobey family rules, will now have children instead of buying conventional assets. This is consistent with the already mentioned empirical evidence that aggregate household saving responds positively to government provided old-age security, and negatively to government deficits. It also explains why fertility responds negatively to publicly provided old-age security.

Family Theory: Economics of Marriage and Divorce

Abstract

This article summarizes the economic approach to marriage and divorce. The economic gains from marriage arise from sharing and coordination. Durable and mutual care help to support efficient outcomes. The gains from marriage and their division influence the decisions to marry and to stay married. Competition in the marriage market determines who will marry whom and the division of the gains. Complementary marital traits lead to a positive assortative matching. Frictions and search explain why, in any given moment in time, part of the population is single and why individuals enter into imperfect unions that dissolve when a better match is found or an unanticipated shock occurs.

From an economic point of view, marriage is a voluntary partnership for the purpose of joint production and joint consumption. As such, it is comparable to other economic organizations that aim to maximize some private gains, but are subject to market discipline. This article describes the working of the marriage market, as a feedback system in which the aggregate divorce and marriage rates influence and are influenced by individual choices, and explains the features of this market that have led to the sharp increase in marital turnover.

The Gains from Marriage

The economic analysis of the family naturally begins with the gains from marriage. These gains are a major determinant of the decision to form a new union or to break an existing relationship. The main economic advantages of being married, rather than being single, are as follows:

1. Children. Although children can be produced and raised outside the family, the family has a substantial advantage in carrying out these activities. There are two interrelated factors that cause this advantage: by nature, parents care about their own children and, because of this mutual interest, it is more efficient that the parents themselves determine the expenditure on their children. Because children are viewed as a public good by their parents, an efficient allocation of family resources between public and private uses requires some coordination between the parents. If the parents live separately, as either single or remarried, the noncustodian parent loses control of child expenditures and is less likely to contribute. In addition, lack of contact may reduce the parent's benefits from the children's 'quality' (i.e., their well-being and success).
2. Division of labor. Family members coordinate their work activities to exploit comparative advantage and increasing returns. For instance, one partner works in the market while the other works at home. This pattern is economically efficient if the partners have different market wages or different productivity at home. Such differences may be inherent or, more likely, acquired through investment in skills. Investment in human capital is more profitable the higher its rate of utilization. This type of increasing returns leads to specialization that can, in principle, create mutual gains through redistribution.
3. Sharing. There are collective (nonrival) goods that can be jointly consumed by both partners: for example, child quality, common leisure activities, housing expenditures, and shared information. The share of such public goods in family expenditures can be substantial. Lazear and Michael (1980) estimate that two single individuals can almost double their purchasing power by forming a union.
4. Credit and investment. Married partners often engage in implicit loans that facilitate investment activities. For example, one partner works when the other is in school, expecting to share in the future gains from the investment. Similarly, parents often finance the schooling of their children, in part in the anticipation of old-age support. Such internal transfers can support investments that are mutually beneficial and would not be carried out because of market imperfections.
5. Risk pooling. A family can spread the risks of idiosyncratic shocks to individual members. For example, one partner can work when the other is sick or unemployed. The family jointly accumulates precautionary savings that can serve either member in case of need.

Realization of these potential gains from marriage requires coordination between the two partners and durable relationship. Durable relationships are motivated by the long-term investment in children and the accumulation of marital capital, which is lost or diminished in value if separation occurs. However, to induce the actions that generate the gains from marriage, it is necessary for the partners to exchange commitments. For instance, a young wife is unlikely to support her husband by working while he is in medical school, if she expects him to leave her and marry a young nurse when he gets his degree. To some extent, emotional factors such as love and guilt replace formal commitments and facilitate efficient investments and effort levels. As an example, consider the role of an altruistic family head. Suppose that the head is given control over family resources and can make transfers as the head sees fit. The only requirement for becoming a head is that they should care about all family members, willing to raise their income, whenever the total resources at the head's disposal rise. Under these conditions, selfish family members

voluntarily act in the interest of the group. The reason is that any productive (destructive) action which increases (decreases) total family resources is rewarded by an increased (decreased) transfer from the family head (Becker, 1991).

There is plenty of evidence for division of labor within families. Typically, husbands work more in the market than do their wives. In addition, married men work longer hours in the market and have substantially higher wages than unmarried men. Similarly, married women have lower wages and work more at home than unmarried women. This division of labor is influenced by the higher market wages of males, which are reinforced by their higher participation in the labor market. Over the years, husbands have increased their share in household work and wives increased their share in market work. But the different household role for men and women are still maintained.

The family is not the only organization that fulfills these functions. Markets and government institutions compete with and complement the family in this regard. If all goods and work activities are marketable, there is no need to form marriages to enjoy increasing returns or to pool risks. Similarly, with good medical or unemployment insurance one does not need to rely on one's spouse. Generally, the role of the family varies depending on market conditions and government policies. In addition, human partnerships need not be confined to couples of opposite sexes. One also observes 'extended families' of varying structures that coordinate the activities of their members and provide self-insurance. The prevalence of male–female partnerships has to do with sexual attraction, which triggers some initial amount of blind trust and the production of children. These emotional and biological considerations are sufficient to bring into the family domain some activities that could be purchased in the market. Then, the accumulation of specific 'marital capital,' such as children and shared experience, increases the costs of separation and creates incentives for a lasting relationship. In this sense, there is an accumulative effect in which economic considerations and investments reinforce the natural attachment.

The potential gains from marriage generally depend on the personal traits of the two partners. Some individual traits are complements, and the gains from marriage rise if the partners have similar endowments. For instance, similarity in tastes or education facilitates agreement on collective goods, such as the education of the children. In other cases, the traits are substitutes, and gains from marriage rise if the partners have different traits. For instance, the gains from division of labor and from credit are higher when the wages or incomes of the partners differ.

Family Decision-Making

The existence of potential gains from marriage is not sufficient to motivate marriage and to sustain it. Prospective mates need to form some notion as to whether families realize the potential gains and how they are divided. Because families consist of several members with potentially conflicting interests, there is a question as to how families reach decisions. The old notion that consensus leads to joint maximization of a common objective is too narrow. However, because of their proximity and repeated interaction, it is plausible to assume that married partners reach some sort of agreement that specifies an efficient allocation of resources and a division of the gains. These two principles replace the principle of rationality in individual choices.

In a special case, referred to as transferable utility, it is possible to separate the issues of efficiency and distribution. This situation arises if there exists a commodity (say money) that, upon changing hands, shifts utilities between the partners at a fixed rate of exchange. In this case, the family decision process can be broken into two steps: first choose an action that maximizes a weighted sum of the individual utilities, then use money to divide the jointly maximal outcome. The basic idea is that the partners can agree on most aspects of their choice and restrict their bargaining to transfers of money, which do not detract from total resources.

In general, the problems of efficiency and distribution are intertwined. The family can still be described as maximizing a weighted sum of the individual utilities, but the weights depend on the partners ability to affect the family choice. There is no need, however, to specify a particular bargaining procedure. It is sufficient to assume that partners have different 'decision powers' within the family that may depend on individual attributes, such as earning capacity, subjective factors such as impatience and risk aversion, and on market conditions, such as the sex ratio and availability of alternative mates. The 'collective approach' assumes that partners always reach an efficient outcome and examines family choices under varying circumstances based only on the assumption that the family has a stable efficient rule of behavior (Browning et al., 2014: Chapter 3).

It is empirically testable whether families maximize a joint utility function, whether they act efficiently, and it is also possible to recover the sharing rule from observed family choices. Recent evidence shows that, holding total family income constant, an increase in the income of one member shifts the allocation of consumption goods in their favor. These findings reject the hypotheses that the family maximizes a joint objective, which would imply that within family, allocations are invariant under such redistribution of total resources, but are consistent with both cooperation and noncooperation. However, only cooperation implies efficiency, which yields testable cross-equation restrictions on family demand. Based on data on consumption and work patterns within families, efficiency is not rejected, suggesting that cooperation is the relevant model (Browning et al., 2014: Chapter 5).

In the context of uncertainty, however, efficiency has some further implications. Efficient risk sharing among linked individuals implies that, holding aggregate consumption constant, the consumption of each family member is independent of idiosyncratic shocks such as fall into unemployment or bad health. Stated differently, all individuals in the household are affected by a random shock to any individual income and their consumption levels move together. Here again commitment plays an important role. If commitment is incomplete the consumption of each spouse will depend also the varying 'decision powers' of the partners. Using data from Consumer Expenditure Survey, Mazzoco (2007) finds that full commitment is strongly rejected.

Divorce and Its Economic Consequences

Modern marriage markets are characterized by high turnover; men and women divorce and remarry at higher rates than in the past. However, different individuals have different marital histories; they marry, divorce, and remarry at different rates (Bruze et al., 2011). To explain this variation it is crucial to understand the two-sided aspect of marriage markets. Marriages form and dissolve based on preferences and expectations of two *different* individuals who operate in a 'marriage market' with many competing agents. As time passes, new information on match quality and outside options is accumulated, and each partner decides whether to dissolve the partnership or to continue the marriage. In making this choice, partners must consider the expected value of each alternative, where the value of remaining married includes the option of later divorce, and the value of divorcing includes the option of later remarriage. Divorce occurs endogenously whenever one partner has an alternative option that the current spouse cannot, or is unwilling to, match by a redistribution of the gains from marriage.

The model outlined above yields several testable implications:

1. It is the unanticipated changes in the characteristics of the partners or the quality of match which trigger divorce. It is clear that falling out of love can destroy the gains from the current marriage and cause divorce. It is less obvious how unanticipated changes in personal attributes, such as earning capacity, influence divorce, because they affect both the gains from the current marriage and the outside options. However, the partners were matched, based on their traits as observed at the time of marriage, any unanticipated change reduces the gains from interaction. Thus, if the husband is unexpectedly wealthy, he may seek a better wife, and if he becomes unexpectedly poor, his wife may seek a better husband. Note that both positive and negative 'surprises' can disrupt the marriage.
2. If the gains from marriage are substantial, small shocks will not lead to divorce. Therefore, the probability of divorce will be lower among couples who are well matched. Anticipating that, couples sort into marriage according to characteristics that are likely to enhance the stability of the marriage. In this respect, the decisions to marry and divorce are linked.
3. By the same logic, costs of divorce mitigate the impact of unanticipated shocks on marital dissolution. The costs arise from loss of specific capital, such as information about the current spouse, and loss of coordination, especially with regard to child expenditures. These costs of divorce are influenced by the postdivorce transfer of resources in the form of alimony and child support. There are also emotional and legal costs associated with the break up.
4. Somewhat more controversial is the role of divorce laws, in particular whether the legal possibility unilaterally to walk away from a marriage influences the divorce rate. With transferable utility, such a change should only affect the shares in the gains from marriage but not the decision to separate, because the partner who wishes to continue the marriage can compensate the one who wishes to leave by giving up part of the gains from the marriage. Conversely, the person who wants to leave can pay damages to the one left behind. In general, the outcome depends on the ability of partners to transfer resources within marriage and following marriage.

These implications have been tested empirically. There is evidence that surprises matter. Specifically, an unexpected increase in the husband's earnings capacity reduces the divorce hazard, while an unexpected increase in the wife's earning capacity raises the divorce hazard. The quality of match also matters. For instance, couples in which both partners are highly educated tend to be more stable (Weiss and Willis, 1997; Bruze et al., 2011). There is only weak evidence that divorce rates are higher in states where 'fault' is not a prerequisite for divorce (Stevenson and Wolfers, 2007).

The Marriage Market

Individuals in society have many potential partners. This situation creates competition over the potential gains from marriage. In modern societies, explicit price mechanisms are not observed. Nevertheless, the assignment of partners and the sharing of the gains from marriage can be analyzed within a market framework, because an undesired marriage can be avoided or replaced by a better one.

Any market solution is a particular assignment of males to females. The major questions of interest are the following: what types of matches are likely to form in equilibrium; for instance, would a class structure emerge where the rich marry the rich? What determines the rates of marital turnover and the proportions of married and single individuals in society? Does the marriage market operate efficiently and, if not, what type of intervention is required?

The marriage market determines not only the assignment of partners but also the division of resources and activities within the family. As market conditions change, a shortage of suitable partners of a particular kind leads to an increase in their gains from marriage. For instance, there is evidence that an increase in the demand for men, created by faster population growth combined with the tendency of men to marry younger women (a marriage squeeze), has led to an increase of dowries in rural India. In modern societies, up-front payments are rare and market forces are mostly revealed by the division of labor and consumption patterns within families. There is a recent literature in which marital shares are either inferred from marriage patterns, as in (Choo and Siow, 2006; Chiappori et al., 2012) or estimated directly from data on leisure and consumption within couples as in (Chiappori et al., 2002; Mazzocco et al., 2007). Additional information on the (expected) gains from marriage is contained in the decisions to enter marriage and to stay married (Bruze et al., 2011).

Matching models provide a starting point for such analysis. These models investigate the mapping from preferences over prospective matches into a stable assignment (Roth and Sotomayor, 1990; Browning et al., 2014: Chapter 7). Reflecting the assumption that marriage is voluntary, an assignment is said to be stable if no married person would rather be single and no two (married or unmarried) persons

prefer to form a new union. To illustrate, assume that each male is endowed with a single trait, m, and each female is endowed with a single trait, f, which positively affects the gains from marriage, denoted by $z = g(m, f)$. Suppose, first, that z is a public good that both partners can consume jointly. Then, the only stable assignment is that in which males with high m marry females with high f, and, if there are more (less) eligible men than women, the men (women) with the lowest endowments remain unmarried, a positive assortative mating. However, if one assumes, instead, that z can be divided between the two partners, a positive (negative) assortative mating occurs only if the two traits are complements (substitutes). Matching models refer to these two situations as nontransferable and transferable utility, respectively. With transferable utility, a man with low m may obtain women with high f by giving up part of his private share in the gains from marriage. Complementarity (substitution) means that the two traits interact in such a way that the benefits from a woman with high f are higher (lower) for a male with high m than for a male with low m. The type of interaction in the gains from marriage determines the willingness to pay for the different attributes. An important lesson is that in a marriage market, with sufficient scope for compensation within marriage, the best man is not necessarily the one married to the best woman because, with negative interaction, either one of them can be bid away by the second best of the opposite sex (Becker, 1991).

The process of matching in real life is characterized by scarcity of information about potential matches. The participants in the process must spend time and money to locate their best options. The realized distribution of matches and the division of the gains from each marriage are therefore determined in an equilibrium which is influenced by the costs of search and the search policies of other participants. The main ingredients of the search model are as follows. There is a random process that creates meetings between members of society of the opposite sex. When a meeting occurs, the partners adopt a reservation policy where the match is accepted only if it provides expected gains above some prespecified value. Otherwise, they depart and wait for the next meeting to occur (Mortensen, 1988).

Because meetings are random and sparse in time, those who actually meet and choose to marry enjoy a positive rent. An important issue is the division of these rents between the partners. The literature mentions two considerations that determine the division of the gains from marriage: outside options, reflected in the value of continued search, and the self-enforcing allocation that would emerge if the marriage continued without agreement. Combining these two considerations, the sharing rule will be influenced by both the value of search as singles (outside the current match) and the value of continued search during the bargaining process, including the option of leaving when an outside offer (whose value exceeds the value of potential agreement) arrives. In this way, a link is created between the division of gains and the market conditions. For instance, if there is excess supply of women in a particular marriage market, the value of continued search by females is reduced and consequently their share in the gains from marriage declines.

With frictions, there is still a tendency to positive (negative) assortative mating, based on the type of the interaction in traits. If the traits are complements, individuals of either sex with higher endowment will adopt a more selective reservation policy and will be matched, on the average, with a highly endowed person of the opposite sex. However, with sufficient friction, it is possible also to have negative assortative mating under complementarity. The reason for this result is that, because of the low frequency of meetings, males with low m expect women with high f to accept them, and if the gains from such a match are large enough, they will reject all women with low f and wait until a high f arrives (Burdett and Coles, 1999; Shimer and Smith, 2000).

Without frictions, one would expect negative sorting on wages and positive sorting on nonwage income, because the gains from division of labor are larger when wages differ, while the gains from sharing goods are larger when incomes are similar (Becker, 1991). However, empirical findings suggest positive sorting on both wage and nonwage income. In particular, there is a substantial correlation in the schooling achievements of partners to marriage.

Frictions and search explain why, in any given moment in time, part of the population is single, even though there are positive gains from marriage. The aggregate stock of unattached individuals is determined by the rates of entry and exit into marriage implied by the arrival rates of offers and the optimal reservation policies chosen by individuals. These decisions, in turn, depend on the aggregate proportion of singles, because if one meets an unattached person it is more likely that a new union will be formed than upon meeting an attached person, who already has some positive rents. Therefore, the higher the proportion of singles (including divorcees), the higher is the private expected gains from divorce. This type of reinforcement can lead to multiple equilibria, whereby both high and low aggregate divorce rates can be sustained through the induced change in the individual incentives to marry and divorce.

The time pattern of aggregate divorces is consistent with multiple equilibria. For instance, the divorce rate in the USA doubled during the decade between 1965 and 1975, standing at roughly 10% from 1940 to 1965 and at roughly 20% from 1975 to 1995, suggesting a switch from a low to a high equilibrium. Explanations for the timing of the change include the appearance of the contraceptive pill, break up of norms, and legal changes (Michael, 1988). The main conceptual point, however, is that any change in exogenous factors, even a small one, can have marked impact on the aggregate divorce rate, because of the inherent reinforcements in marriage markets.

Broadly viewed, divorce is a corrective mechanism that enables the replacement of bad matches by better ones. The problem, however, is that private decisions may lead to suboptimal social outcomes because of the various externalities that infest search markets. These externalities exist at the level of a single couple and the market at large. In the models outlined above, those who initiate the divorce fail to internalize the interest of their spouse in continued marriage and the custodial mother that remarries fails to internalize the impact on the father. Moreover, children may suffer even if their welfare is fully internalized, because the child's welfare is only one consideration in the parents' marital choices. At the market level, a person who chooses to divorce fails to take into account the impact on the remarriage prospects of others, and if commitments are made, on the quality of prospective mates.

Some Policy Issues

Despite its firm roots in nature and its antiquity in human society, the future of the family institution has been recently put into question. This was motivated by recent trends, common to all Western societies, of declining marriage rates, declining fertility, higher divorce rates, and a rise in alternative arrangements such as cohabitation, single-parent households, and single-mother families. Social observers view these trends with considerable alarm especially because of the potential harm to children (more than one million children in the USA are involved in a divorce every year).

Although there is ample evidence that divorce reduces the welfare of single wives and of children with single or stepparents, this is only one part of the picture. Continuation of marriage under adverse conditions can have equally harmful results, although these are harder to identify.

It has been observed that divorced husbands, even if relatively well to do, fail to support their exwives and their children at the standard to which they were accustomed during marriage (Weiss and Willis, 1997; Chiappori and Weiss, 2007). Consequently, divorced women and children in their custody suffer a large decline in income. The possible explanations for this phenomenon are: lack of binding marriage contracts, the inability of noncustodial parents to monitor expenditures by the custodian, and loss of interest in the child by the noncustodian parent. In most cases, the wife obtains custody and controls the expenditure on children. This situation creates an agency problem, because out of every dollar transferred to the custodial wife with the intention of raising the welfare of the child, part is used for her own consumption. Because of this 'tax,' noncustodial fathers reduce their transfer, and consequently child quality is reduced. The assignment of custody to the wife is usually motivated by her comparative advantage in child care, but the agency problem implies that such a practice has shortcomings that are not easy to overcome, because the courts cannot verify within-household allocations.

The adequacy of transfers must be judged not only on the basis of the efficiency of allocation of family resources in the aftermath of divorce, but also on the basis of partners' options and expectations at the time of marriage. From the latter point of view, efficiency requires that the consumption levels during marriage and divorce are tied together. Courts do take into account these two broad considerations in awarding divorce settlements. These are usually based on postdivorce incomes and the accustomed consumption of the wife and children during marriage. However, the evidence suggests that actual transfers fall short of the efficient level from both the ex post and ex ante points of view.

With deficient transfer mechanisms, the partners must better prepare for the event of divorce. One important instrument is the allocation of time within marriage. By investing in human capital, each partner can be less dependent on transfers in the event of divorce. However, such investments may detract from marital output. For instance, a wife who works is better defended against divorce but has less time to spend with children. Indeed, there is evidence that women tend to increase their investment in market work in anticipation of divorce. Thus, if the risk of divorce rises, children may suffer even before the marriage breaks (Browning et al., 2014: Chapter 6).

Because meetings are random and uncoordinated, the search behavior and the decision whether to marry or divorce of each individual influences the marriage (and remarriage) prospects of all other members of society who are potential matches. Therefore, legal intervention must take into consideration the impact of the law not only on particular families but also on the marriage market as a whole. These two considerations may be in conflict. As an illustration, consider an increase in the size, or the enforcement, of child-support payments. Holding the aggregate divorce and remarriage rates fixed, each family in isolation may be better off as a result of the additional insurance. However, the reduced propensity to divorce can have a negative effect on the remarriage prospects of those who have suffered a large negative shock to their quality of match and who wish to separate. Another externality that must be considered, and may operate in the opposite direction, is that the availability of alternative mates can reduce investments that are specific to the current match and detract from its quality. This is indeed the logic behind the laws and religious norms aimed at restricting divorce.

The links between poverty and family take a particularly strong form in the black communities in the US. It has been argued by Wilson (1987) that black women delay or avoid marriage and have children out of wedlock because of a shortage of marriageable black men with a steady job and good income. As pointed out by Willis (1999), low-income men may also forego marriage in order to father children out of wedlock with low-income women who voluntarily bear and rear these children. This type of analysis illustrates the general point that it is not simply the number of men and women that determines marital and fertility outcomes but also their respective distributions of traits. Moreover, shifts in the distribution of traits of men can affect the marriage behavior and work behavior of both men and women. For instance, Seitz (2009) shows that if black men had the same wage distribution as whites, they would work more than black women (as among whites) and, surprisingly, the fraction of marriages in the black population would decline. This occurs in her simulations because the decision power of black women within marriage declines and, consequently, the share that the wife receives from the marital gains declines too when black men receive higher wages.

The observed changes in family arrangements are closely related to the dramatic changes in labor-market participation and education of women, and the associated technological advances in the workplace and in the home. Whatever the causal relationships, it is clear that these processes reinforce each other and generate complex dynamics. While the reduction in marriage has been fairly smooth, the changes in divorce appear discontinuous, suggesting search externalities and perhaps the breaking of norms in the processes governing divorce and remarriage. These abrupt changes cause a special adjustment problem that requires social and legal restructuring. However, the expected outcome for the early twenty-first century is that the marriage market will settle at a new equilibrium with higher marital turnover, reflecting the lower gains from marriage as the disparity in the market productivity of men and women gradually declines. Although reduced, the gains from marriage are unlikely to disappear and the family, in one form or another, will continue to have a major role.

Abstract

Fashion is a social phenomenon *par excellence*. A simple sociological definition of fashion is 'being first with the latest.' Its underlying principle is revealed in the link between the *modus* derivatives and the term 'modern,' with its original meaning of 'now' or 'for today.' Fashion revolves around imitation and diffusion, and it applies to all domains of social life, though most of the research is on garments. The field of fashion has been neglected, but since the mid-1990s, it has attracted sociologists studying production of fashion, identity, and the body in relation to fashion. What is lacking is theory development.

Introduction

Fashion is a social phenomenon *par excellence*. As a phenomenon it may be as old as mankind, but became common with the emergence of consumer society in the nineteenth century. It was then that social scientists started to show interest in fashion. A simple sociological definition of fashion is 'being first with the latest.' The definition implies that fashion is about change, and that an object, style, or activity stands out against a backdrop of stability. A fashion is understood as being right in a specific time and context. What is right is 'defined' by a clique of people, fashion leaders, who others see as having the status to determine what is in fashion. Fashion needs followers, but it is also necessary that some people are out of fashion, since not everyone, or everything, can be 'in fashion.' In fact, once something is too common it is likely to be replaced; if not, fashion cannot be used to make distinctions. Thus, fashion is a recurrent phenomenon that creates its own history, from which ideas may be reused or reinterpreted.

While the word 'fashion' in English comes originally from the Latin *facere*, to make, in many European languages it derives from *modus*, to measure. From the sixteenth century, fashion refers to conformation to existing taste, which is also when the notion got a more contemporary meaning. Mode refers to manner, and there is a strong connection to 'modern' and 'modernity,' concepts that are connected to capitalism and development. Its underlying principle is revealed in the link between the *modus* derivatives and the term 'modern,' with its original meaning of 'now' or 'for todays.' Fashion is a general social phenomenon of diffusion, but which in both everyday life and in the social sciences mainly means garments, and in particular haute couture. However, already Blumer outlined a much larger scope of fashion: "painting, music, drama, architecture, household decoration, entertainment, literature … medical practice, business management, political doctrines, philosophy, psychological and social science, and even such redoubtable areas as the physical science and mathematics" (Blumer, 1968:342). It is, in fact, hard to *a priori* exclude an area from the analysis of fashion.

Fashion is different from innovation, style, and trend. Fads refer to processes of diffusion of things or activities that normally include many actors, such as when the skateboard was introduced. Fads do not have a history of replacing each other. Fashion, furthermore is different from innovation. Both fashion and innovation replace something existing, such as an older fashion or an existing practice or technique, but innovations permanently alter the social practice or things, for example, the material people use to insulate houses. An innovation, hence, has lasting effects, and may be seen as a progress according to a scale of evaluation. Fashion is different from style, which refers to a multidimensional self-referential aesthetic system produced and extended over. The styles of punk or Goth are examples. A trend, finally, is a process with an identifiable direction over time, such as when people are dining out more frequently. A trend, for example, of how one should present food, thus, may encompass several fashions, of where one 'should' eat out in various cities.

Fashion was once a limited phenomenon, with very few in a society able to participate. In modern societies, however, economic well-being has made it possible for the vast majority in many countries around the globe to participate in the 'fashion race.' Wealth is not the only factor; however, people also enjoy far greater psychological mobility, and the new form of communication it generates makes fashion more important today. In *Psychologie économique* (1902), Tarde coined the term 'inter-psychologie.' Society is the sum of people's mental condition in constant interaction. Free time and consumption become increasingly significant vehicles for such communication. New needs are born out of this mental interaction.

Social science research has for almost 100 years treated fashion as a field of lesser importance. Researchers, not the least sociologists, have over the last 15 years paid more attention to fashion, especially to the production of fashion, and there is today also an emerging discipline called fashion studies. It is at the same time clear that the field needs more theoretical development.

Fashion in Different Societies

Fashion's universal nature does not preclude strong variations in its social significance from society to society. Thus, Tarde (1903) differentiated between customary and fashionable

societies. In the former, people see *custom* as governing their lives; they are more passionate about their country than about their period because custom prizes the past above all. In periods where *fashion* predominates, people are instead prouder of their era than their country.

Variations between societies are thrown up by different conditions. In economically stagnant periods, conventional stratification variables such as class and income are more decisive in people's lifestyles. In economically expansive periods, increasing importance is laid on fashion instead. Modern society is often contrasted with earlier epochs, and it is argued that fashion's role has markedly increased, although many reasons are given for the change. An influential argument is that the differences in lifestyle of different groups have increased in number and scope, making it possible for people to exhibit their group's distinctive nature.

Simmel sees the 'need for distinction' and the 'need for union' as preconditions for fashion. Certain societies therefore lack the necessary motivation. Simmel (1904) mentions that in fourteenth-century Florence, male dress was devoid of fashion. The 'need for union,' the need to express how certain groups were distinct from others with the help of fashion, was absent, and everyone could dress according to personal preference. Another of Simmel's examples was Venice at the same time. Again, we find that fashion is absent from upper-class dress. Venetian aristocrats were ordered to dress in black so that the lower classes would not know how few they were. They did *not* want to differentiate themselves, and thus the 'need for distinction' that fashion requires was missing. Their 'uniform' can be interpreted as one dimension of what constitutes their status group, as Weber would call it.

Variations in fashion's importance have also been tied to women's standing in society. According to Veblen (1899), it was woman's role to be a vicarious consumer; her consumption symbolized the man's wealth, and thus she became the vehicle of fashion. In Simmel (1904), however, we find an early formulation of compensation theory. Fashion acts as a safety valve. Deny women self-expression in other areas, and the only thing left for them is fashion. In fourteenth- and fifteenth-century Germany, the chance of personal development had increased, which, however, was denied to women. Rarely have more 'hypertrophic' modes of female dress been seen than in this period.

Simmel (1904) further explains fashion differences between societies. Fashion has two fundamental, symbolic functions: an ability to mark difference and an ability to express community. In many nonindustrialized societies, the need for union is acute, while the need for distinction is weak. Simmel mentions certain African tribes who lacked both class differentiation and the concomitant need to signal differences. Where people in these societies want to note differences, it is often a matter of open hostility, which in turn is sterile ground for fashion. Given that fashion functions best where the distance between groups is otherwise only vaguely established, in instances where open hostility already exists, fashion as a sociological form becomes meaningless.

A similar argument can be found in König (1974), who identifies three different stages in society, each with a different type of fashion. The first significant historical change was the emergence of a fixed class hierarchy; at this stage, fashion is the preserve of exclusive, feudal nobility. In the second stage, rigid differences between upper and lower classes are weakened; lower classes adopt the fashion of the elite, ultimately forcing it to alter fashion constantly to retain its individuality. The third stage sees the development of egalitarian democracies and industrial technology. This modern form of society brings with it the spread of fashion through mass consumption.

Fashion as a Process of Change

Fashion is about change, but this change presumes that other things are ordered; if not, changes would not be perceived. The question of what drives fashion's continuous changes has kept researchers busy, and a series of different theories has been given in answer. In Simmel's analysis of fashion, we find a foretaste of many of the theories that were to follow.

Social Differentiation

Many have stressed fashion's origins in class. Though class has its origin in production, its cultural and symbolic meaning is expressed by means of consumption. The analysis by Veblen (1899) of patterns of fashion dispersal has become a classic. A fashion begins with the 'leisure class,' the group with most money. It is attractive to this class because fashion items cost a great deal more than regular items. By degrees, the fashion is adopted by the upwardly aspiring middle classes. Simmel (1904) also describes how fashion must constantly be supplied with new content if it is to give social expression both to similarities within groups and differences between them. To describe fashion's downward spread through society, the *trickle-down* model was adopted by Barber and Lobel (1953), who dismissed the argument that fashion is irrational as obscuring its connections with the economic system. Meanwhile, named for the imitation of the elite that brings in turn an alteration in elite habits, we have the chase and flight model.

Bell (1976) follows Veblen in seeing economic competition as a force behind changes in fashion. Dress for the middle and upper classes is an expression of wealth. This wealth can be expressed in the form of *conspicuous consumption*, *conspicuous leisure*, and *conspicuous waste*. To these, Bell adds his own category of *conspicuous outrage* to convey the fashion-setting class-conscious choice of clothing that does *not* conform with prevailing notions of good taste.

The theory that fashion is the means of social distinction for the upper classes in a hierarchical society has had great influence. Mimicry of social superiors and an urge to be different from 'inferiors' are often noted as the reasons for fashion's changes, while an individual's choice of style is seen as a significant means of securing his or her position in society. Such choices often establish their distance from those below them in the social pecking order and express subtle distinctions of degree within one and the same class. Researchers who present other models often start from the theory of social differentiation, even if they distance themselves from its application to today's society. Some argue that the idea that fashion was the distinguishing mark of the elite was probably valid in the eighteenth and nineteenth centuries, but this is less

so today. It has been argued that the traditional upper class has lost its fashion primacy to be replaced, for example, by today's powerless elite. This new elite, termed *Divi* by Alberoni (1967), uses the mass media to present new lifestyles and new consumption. Theories stressing that ideas through the means of trend scouts also move from the street to the designers and thus affecting or even determining fashion have been presented. Others have discussed how subgroups, for example, Goths (Hodkinson, 2002) have developed their own fashions. It is nonetheless fair to say that one cannot speak of one fashion only, but of fashions.

Fashion's Inner Dynamic

Simmel's analysis included a further suggestion of what drives fashion. Fashion is made up of internal, conflicting forces that necessarily lead to change; it is distinguished by differentiation *and* union, superficiality *and* profundity, freedom *and* dependence, individuality *and* imitation, destruction *and* construction, leadership *and* submission. Antagonistic forces are united in fashion in a way that ensures continual change. Nedelmann (1990) develops the idea of the inherently contradictory nature of fashion, describing its *Eigendynamik*. Fashion, by its nature, contains a stimulus for change derived from polar opposites. People like to imitate, thus spreading a certain fashion, but are equally drawn to differentiation. Imitation leads to the spread of fashion, while new ideas and differentiation lead to its contraction. Nedelmann invokes Simmel, writing that the greater the degree of concord within the upper classes, the more frantic the search for imitation from beneath, and the more constant the search for new fashions by the upper classes. On the other hand, the more the members of the lower classes use style to differentiate between themselves, the less the upper classes are inclined to come up with new fashions. Fashion in this society thus has less significance.

Davis (1992) has also noted the ambivalence of fashion, and identifies its source in sexuality. Davis writes of a continuous dialectic in clothing between the erotic and the modest. Sellerberg (1994) similarly stresses the significance of antagonism as a driving force of change. Fashion reduces *and* creates complexity. It is a continuous break with authority, but its break is authoritative: 'this is what matters, for now.' In this contradiction one finds the motor of change.

System Theories

Davis (1992) differentiates between two types of sociological model used to explain the dissemination of clothing styles. The first, the *populist* model, centers on the consumer's role and the laymen's innovations in dress. Researchers who use the populist model study general consumption, for example, how groups such as teenagers, surfers, gays, skateboarders, or feminists set their own stamp on fashion. The other model is a *system* model. Some system models are predicated on the existence of established social centers for innovation, for example, Paris or Milan, with their fashion shows, designers, editors, wholesalers, and stylists. The fashion system is here seen as a closed circle of producers, distributors, and consumers (Kawamura, 2004).

The trickle-down theory has been criticized by system theorists because it does not focus on the complex structures of organizations and marketing that channel and mediate the fashion process. Those who use a system model aim to analyze the influence of the different elements of the fashion system. One subject of controversy has been whether designers are creative interpreters or merely passive intermediaries in the commercially vital process of heeding consumers' wishes and reconciling them with the producers' requirements.

Fashion as a Break with Convention

The destruction of what exists and the construction of something new in the process are the elements that unite in fashion, according to Simmel. Researchers who today see fashion as breaking current rules usually identify groups other than the socioeconomic upper class as leading fashion. Campbell (1992) has criticized the class differentiation theorist's explanations and identifies different types of 'new': the new, the innovative, and the novel. The novel – new as different – is central to fashion as it breaks with what already exists. The necessary conditions for creating novelty exist in peripheral groups such as bohemians and artists. It is these groups who set fashion in motion, *not* an upper class. To argue that fashion is unconventional, however, is also to argue that fashion continuously reestablishes social conventions and social order. Blumer (1969) sees both similarities and differences between fashion and custom. In both cases, it is a question of social ordering. Custom, however, is static or changes only slowly, while fashion is a constant creator of social order. In Blumer's argument, every fashion emerges from an intensive process of 'collective selection.' The alternatives that are ultimately selected become fashion in different areas. Fashion conjures order out of the vast jumble of possible styles where no objective norm can determine 'right' or 'wrong.'

Fashion as a Psychological and Social Expression

Psychologically oriented theories of fashion frequently center on general human needs such as the wish to be appreciated. It is often pointed out that people's need to display and strengthen their ego is particularly strong. Fashion has great shock value in the hunt for self-expression; it provides a tangible 'look at me.'

In a discussion of fashion as an expression of personality, we can return to Simmel. Fashion makes it possible to express opposites. While conveying personality (paradoxically in the extreme imitation of the modern), it also offers the chance to *avoid* conveying individuality, and thus functions as the ego's 'iron mask.'

Fashion offers a means of psychological expression, but also a social expression of protest. People express in fashion the impulses and wishes that are *not* sanctioned by normal social conventions. There is thus a constant tension between the more established 'domain of culture' and the marginal 'domain of fashion.' In fashion, young people express their stance through wearing what König (1973) calls 'anti-fashion.'

The idea of fashion as a vehicle of social protest has been criticized, however. Protest styles are usually incorporated into fashion and exploited economically (Emberley, 1987).

Others argue that fashion's break with convention is actually a pseudodeviation. Although certainly defying convention, each break loses its original edge as soon as it is expressed in fashion (Wilson, 1985).

Fashion has been interpreted as an expression of the search for a personal identity in an insecure world, and 'fads and fashions' as an expression of the worry that typifies our time. This has sometimes been interpreted as a negative phenomenon. Blumer (1969) thinks that the operation of fashion becomes natural in a changing world where people must continuously cut their ties with the past. Individuals are liberated from earlier models, and orient themselves toward the future. The importance of fashion is as clearly seen among those who follow or try to determine fashion, some of whom turn into 'fashion victims,' as among those who actively argue for an antifashion. Regardless of which attitude a person has, it is hard to stay 'outside' of fashion.

The Production of Fashion

Fashion is not only an effect of the increasing wealth, it is a social phenomenon that drives the economy. Since the mid-1990s sociologists have studied the production of fashion, and looked into the conditions and effects of how fashion is produced. This research has focused on the garment industry, but in contrast to much of the earlier sociological work, consumption and social distinction have not been in the foreground. But the focus has not only been on garment production, but on the institutions, actors, and logic of fashion production – how it comes to be that some garments, models, photographers, or styles come into fashion, and others not (Entwistle, 2009). The general point being made is that fashion is a collective, though not a concerted, product, and that various producers, including, designers, models, fashion photographers, magazines, buyers, and many other coproducers of fashion, are involved in this production. Several authors have contributed to this field. One study that represents this field of research is a sociological analysis of fashion with a focus on global garment markets (Aspers, 2010). The study shows how the final consumer market for fashion garments in Western Europe is intimately tied to the markets for production of these garments, located in countries where the cost of production is low. Others have studied fashion magazines (Moeran, 2006) and what they do to affect the current fashion and fashion models. The fashion industry is one of the largest in the world, and the economic side of fashion, however, is not only restricted to garments.

Fashion's Cycles

Some researchers have been less interested in fashion's social dynamic than in an in-depth descriptive study of its cycles. Richardson and Kroeber (1940) use empirical data to identify six different formal aspects in women's dress taking, for example, the changes in length and width of skirts over 300 years. A number of researchers have followed Kroeber's empirical tradition, in which specific changes in fashion are seen to occur within a continuous cycle of longer periods. For example, Robinson (1976) studied beard fashions between 1842 and 1972 as time series analyses. To understand the elapse between the reappearance of the same fashion, Robinson argues that certain ground rules apply for fashion's cyclical changes, one being that as long as a number of people still follow a certain fashion, it prevents younger people from adopting it.

Fashion in this perspective is not born, but is rediscovered. Cross-cyclical changes receive particular attention as demonstrating sharp reactions to extreme styles. For example, the streamlined form's soft curves are contrasted with the ensuing period's particularly angular design. Cycles are not only restricted to garments. Stanley Lieberson (2000) has shown that personal names have a strong cyclical pattern.

Ambivalence Toward Fashion: The Vitally Unimportant

Fashion is dubious, and especially economists, for example, Pesendorfer (1995) have often criticized fashion for being the primary example of irrationality – and thus something that should be abolished. Fashion's symbolic significance has been contrasted with its lack of practicality. This has led many today to express ambivalence toward fashion, and there is a tendency to legitimize it using functional arguments; the rational and practical is acceptable where the impractical is not. Function and symbolism can sometimes be reconciled in fashion, however. Aerodynamics has been described as a discovery of great significance for industrial design, and for a time all household appliances were streamlined. 'Streamlining' symbolized America's enlightened practice of throwing over old conventions to create a new and dynamic civilization. Those who chose, for example, a streamlined kettle, demonstrated that they also chose the rational, the future, and the practical.

Fashion as Unpredictable

Increasingly, fashion's analysts, as stated by Aspers and Godart (2013) have come to emphasize the inner dynamic in fashion. Individual theories are run together to reflect fashion's inherent contradictions: it is coercion *and* individual choice; it is social order *and* a break with social order; it is union *and* differentiation. The nature of fashion is seen as ever more complex.

There is a more simplistic perspective, however, common to those who base their interpretation of fashion on industrial products. Here one finds phrases such as 'the most thorough logic of planned aging,' and 'industry is based on extolling a perpetual neology.' Fashion, however, is to be found everywhere, not only in areas that are subject to commercial planning, while the aging of fashion is impossible to predict precisely, however much industry demands precise guidelines. The problems stem from fashion's most central characteristic: because it symbolizes 'now,' it can never be foreseen with any certainty. Fashion pinpoints what is right in the present, but the moment it can be predicted accurately, it is no longer a matter of fashion. The transient symbols of what is right for now can never be nailed down in advance.

Fatherhood

Abstract

Interest in understanding fatherhood has grown in industrialized countries as men have become more involved in rearing children. This appears to be a continuation of the gender revolution that was seen as stalled because, as women reduced their household work, men did not appear to take up the slack. In contrast to other forms of work at home, involvement with children has high rewards. Men's increased involvement will contribute to improving family life in the future because of the benefits it can bring to themselves and their families. This brief article summarizes some of the current knowledge and issues in fatherhood research.

Interest in understanding fatherhood has grown enormously in industrialized countries, starting in the final decades of the twentieth century, with a vast increase in the numbers of publications and a new journal on the topic (*Fathering*). In part, this reflects the growing complexity of men's fatherhood experiences as union dissolution became more common, increasing the proportions of absent fathers and stepfathers, as well as the small numbers of male custodial parents (Goldscheider and Sassler, 2006). Also, of course, the interest in understanding fatherhood reflects men's increased involvement with their coresidential, biological children (Furstenberg, 1988; Hofferth et al., 2013) as well as their noncoresidential children (Amato et al., 2009), together with the recognition that this is important for both children and fathers (Pleck, 2007; Eggebeen, 2001).

The Gender Revolution and Changes in Fatherhood and Motherhood

At the broadest historical level, the increase in involved fatherhood and the growth in scholarly interest reflect the 'second half' of the gender revolution in the more industrialized countries (Goldscheider, 2012). In the first half, once thought of as the only gender revolution, the extremes of the separate spheres of the 1950s and women increasingly joined men in the public sphere, the labor market. Given their increased education and potential earnings and the stagnating earnings of men, they could better provide for their families' needs in the workforce than they could by remaining in the home. The second half, however, which many find to be 'incomplete' (Esping-Andersen, 2009), 'unfinished' (Gerson, 2010), or even 'stalled' (Hochschild and Machung, 1989; England, 2010) is now underway across the industrialized world, and consists in men's increasingly participating in the private sphere of the home (Kan et al., 2011).

Most studies of men's increased involvement in the tasks of the home that became difficult for women to manage as their employment levels increased, with longer hours and younger children, have focused on housework, with child care often ignored (Sullivan, 2013). However, as many have recognized, time with children is experienced as far more personally rewarding than other household tasks (Krueger et al., 2009). Most people also find housework easier to outsource or forego than child care, hence the growth in meals away from home and carry-out restaurant food, as well as the decline in food preparation and overall housework time (Raley et al., 2012). In contrast, people attempt to minimize outsourcing child care to the hours both parents are at work, pursuing active parenting to the extent possible; fathers now spend as many or more hours with children as mothers on weekends (Yeung et al., 2001).

This trend toward men's greater involvement in the tasks of the home, now advancing in all industrialized countries, has been strengthening families, reducing union dissolution (Oláh and Gähler, 2014) and 'lowest-low' fertility (Kaufman, 2000; Torr and Short, 2004; Duvander and Andersson, 2006). However, the many decades that separated women's increased entry into the public sphere and men's increased involvement in the private sphere were difficult for families, reducing fertility (Waite and Stolzenberg, 1976) and increasing union dissolution (Ruggles, 1997). As a result, men and women have become less committed; they exit relationships more easily and increasingly choose to cohabit rather than marry, even as they pursue parenthood (Cherlin, 2010). Our view, that the second half of the gender revolution will lead to increasingly stable families with more children, differs from the more prevalent theoretical approach, that of the second demographic transition (SDT), which predicts continued family weakness, with high levels of nonmarriage, nonparenthood, and cohabitation (e.g., Lesthaeghe, 2010). Another change over the past decade that may be strengthening committed family relationships, particularly for children, is the increased acceptance and now legitimation in many states of same sex relationships and the increased proportion of these new couples who are rearing children (Williams Institute, 2013).

Nevertheless, both the SDT and gender revolution approaches recognize that an important consequence of the increase in female labor force participation was a sea change in the relationships between men and women that upset the low divorce, high fertility regime that characterized so many industrialized countries in the decades immediately after World War II. As a result, too many children have had to deal with their parents' unstable relationships, with absent fathers (and increasingly absent mothers), and with their custodial parents' new coresidential relationships.

Changes in the Living Arrangements of Children and Parents, 1996–2009

The most recent changes in the coresidential arrangements of children (less than 18) and parents are shown in Table 1, revealing the continued growth between 1996 and 2009 in the proportion of children living with unmarried (and often nonbiological) parents and the decline in the proportion living with two, married biological parents. Overall, the decline in living with two parents was a relatively small 2% points (from 73.4 to 71.4%), although the decline in the proportions living with two married biological parents was larger (4.1% points). Hence, the overall decline was offset by the growth in living with parents in less traditional relationships: unmarried biological parents, which increased from 1.8 to 3.2%; a married biological parent and a stepparent, which increased from 6.7 to 7.1%; and the least traditional parental structure, two unmarried parents, only one biological, which increased from 2.5 to 2.8%.

There was much less change in the proportion of children living with a lone parent, which increased overall from 22.7 to 24%. Most of this increase was due to the increase in children living in father-only families (from 2.1 to 3%); the increase in the share of children living in lone-mother families was much smaller, from 20.6 to 21%. Finally, likely reflecting the early impact of the Great Recession of 2008, there was also an increase from 3.9 to 4.6% in the share of children who were not living with either of their parents and were likely living with grandparents or other relatives, or were in the foster care system.

It is likely, however, that these relatively small changes, mostly continuing the trend over the past several decades, would look different with a control for social class, given the increased inequality of life chances and family relationships that have characterized the United States in recent decades. Children of parents who have at least some college education are far more likely to be living with both biological parents, particularly married parents (McLanahan, 2004). Given the increased recognition of the importance of fathering for children, these changes have put the children of less educated parents at considerable risk.

Table 1 Percentage of children <18 living with parents, 1996 and 2009

Family type	*1996*	*2009*
Two-parent family	73.4	71.4
Two married, biological parents	62.4	58.3
Two unmarried, biological parents	1.8	3.2
Two married parents, one nonbiological (step)	6.7	7.1
Two unmarried parents, one nonbiological	2.5	2.8
One-parent family	22.7	24.0
Mother only	20.6	21.0
Father only	2.1	3.0
No-parent family	3.9	4.6
Total	100.0	100.0

The Transition to Fatherhood

Most men eventually become fathers. However, early fatherhood and less conventional fatherhood are more common among men of lower socioeconomic status or unstable family backgrounds. Men who experienced an unstable childhood family have been found to transition to biological parenthood early, particularly to nonresidential fatherhood and, among residential fathers, to cohabiting fatherhood rather than married fatherhood (Hofferth and Goldscheider, 2010).

Further, men who experienced a disrupted family structure in childhood were both more willing to become stepfathers (Goldscheider and Kaufman, 2006), and more likely to do so (Goldscheider et al., 2009). Entry into single fatherhood is also influenced by childhood family structure. Having experienced four or more parental transitions as a child was associated with a male being likely to become a single father (Hofferth and Goldscheider, 2010).

Motivation for and Barriers to Father Involvement

Father involvement encompasses three components: (1) engagement, (2) accessibility, and (3) responsibility (Lamb et al., 1985). Engagement is fathers' direct interaction with children, such as bathing, playing games, and reading a book. Accessibility refers to the ease with which the father can be reached, such as being at home in another room or contactable by phone. Responsibility is the extent to which the father is involved in managing care for the child, such as making doctor appointments, buying clothes, selecting and coordinating child care, and arranging after school activities. In addition, researchers often incorporate measures of the quality of father–child interactions or relationships (e.g., warmth responsiveness and control) in definitions of father engagement (Pleck, 2010).

What are fathers' motivations for involvement? The literature has conceptualized motivations as biological/evolutionary and psychosocial. Men are motivated to father and rear children in order to maintain the family line; this implies also that men will be more motivated to spend time with biological children, as they have the best long-term payoff in evolutionary biological terms (Waynforth, 2013). In humans, the motivation may be to improve the chances of securing a new partner, that is, a mating investment. Males of many species have been shown to parent nonbiological offspring (Hofferth and Anderson, 2003), so involved stepfathers are not unique.

Situation/structural and legal barriers to father involvement are numerous. These include inflexible employment schedules, strong gender-role stereotypes, and legal divorce settlements that limit fathering rights to biological fathers (Pleck and Masciadrelli, 2004). Research has shown that father involvement is strongly influenced by the mother, both in terms of gatekeeping and modeling, but mother involvement is less dependent on the father (Hofferth and Pleck, 2008).

Paternal Influences on Child Development

Because of the difference in access to children who are nonresidential, the literature has generally separately examined

the influence of fathers on children according to whether or not the father and child are living together. Among those who coreside, the literature classifies, first, whether or not the child is a biological child of the father and, second, whether or not the parents are legally married.

Level of achievement and behavior problems are the most commonly explored developmental outcomes associated with father involvement. Among residential fathers, more research supports the association of parenting with child behavior than with child achievement. Children living in stable two biological married parent families uniformly have better behavioral outcomes than children living in other family types. The benefits include greater economic resources, more effective parenting, and more stability. Most research suggests that fathers contribute independently, although the specific contribution often depends upon characteristics of the child and of the couple relationship. A recent study indicates that positive paternal interactions and warmth for the child reinforces maternal supportiveness of the child. Mothers' parenting is not as effective in reducing toddlers' behavior problems without paternal support (Verhoeven et al., 2010). Another recent study suggests that paternal presence is much more important in reducing child behavior problems when the child has a difficult than an easy temperament (Cabrera et al., 2014). It truly is the interaction between two well-functioning parents taking the child temperament into account that matter to child behavior. Although biological parents have advantages, the research suggests that stepfathers can be excellent partners and parents. The benefits of living with the biological father also appear to extend to unmarried biological fathers. Such fathers tend to be younger and less advantaged; controlling for these differences reduces the disadvantage to the child. Only in recent years have there been sufficient numbers of families in which to examine this association (Hofferth, 2006; Hofferth and Anderson, 2003).

Based on a meta-analysis of literature on nonresidential fathers and child outcomes up to the late 1990s, Amato and Gilbreth (1999) found that the provision of child support, greater emotional closeness, and authoritative parenting were consistently associated with greater academic success and fewer externalizing behavior problems, whereas contact was related to academic success but not to externalizing problems. Internalizing behavior was not consistently implicated for any of the involvement measures. Of course, the age of the child is important. Hawkins et al. (2007) suggest that by the time the child reaches adolescence, the involvement of nonresidential fathers may make much less of a difference; at that point, fathers respond more to the child than child to father. Because there are clear differences across study time periods and across child ages, it is time for another such careful meta-analysis to be conducted.

Discussion and Conclusion

Men's involvement in the private sphere of the family and, in particular, the expansion of their paternal roles is clearly proceeding unevenly. Children are increasingly living with parents in unstable relationships, which are less likely to provide the security children need as they are growing up. This is the case for those living with cohabiting biological fathers and those living with stepfathers. There is substantial concern that some men lack motivation or the knowledge and resources to adequately parent their children. Research indicates that parenting has intergenerational consequences; how men were parented matters to how they parent their own children (Hofferth et al., 2012). Yet there are signs of men's increasing commitment to their children, both in terms of fathers' increased involvement with both their coresidential and noncoresidential children and in the growth in children living with their fathers but not their mothers.

Nevertheless, the message from the research and reviews conducted to date on father involvement is that more than biological, marital, or actual residential structure, it is the quality of the emotional relationship between the child and the father that matters the most for the child's behavior, both in childhood and adolescence (Cabrera et al., 2012; Hofferth et al., 2013). Another important point is that parents and children have joint influences. Parents respond to children's behavior and children to the actions of parents, though it is likely that parental influence is stronger on younger than older children. Finally, children's temperament and the mother–father and mother–child relationship also matter and need to be considered. Fathers matter more under some conditions than others, in particular, when a child is less able to control his/her emotions.

Research on same sex couples, whose strengths for child-rearing are mostly unknown, is needed (but see Goldberg and Smith, 2013). Because same sex couples are eagerly marrying and adopting children, this will be an important context for children in the future. Another important area is that of immigrant families. We have not addressed racial, ethnic, generational, and cultural differences in this article. The research does not suggest that the main conclusion about the quality of the relationship mattering most would differ across groups, although attitudes and values regarding the role of the father may vary.

Further, there is little research on whether more intensive fatherhood is leading men to become even more involved in the private sphere of the family. How do varying amounts or types of father involvement affect the likelihood of providing care for sick children, and of providing a healthy environment within which children can develop to their full potential? Finally, fatherhood has been shown to benefit men as well as their families. It is clear that involved fatherhood is an important step in breaking down the separate spheres, further advancing the second half of the gender revolution.

Fathers and Fathering: Social Work Perspectives

Jonathan Scourfield, Cardiff University, Cardiff, Wales, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

'Fathers' is a very diverse category and there is considerable variation in fathering within and between countries. Fathers have not traditionally been the focus of much attention in social work practice, but some committed practitioners are now developing innovative interventions. There is relatively little evidence about which interventions result in good outcomes, but this article attempts to provide an overview of what is known about effective practice with fathers.

Introduction

Men comprise around half the population, but only a minority of the users of social work services. For a variety of reasons, men are much less likely than women to have contact with social workers and this gender difference is perhaps especially acute in relation to child and family services. This article will provide an overview of social work with fathers. It begins by setting the social and cultural context of contemporary fathering, before moving on to critiques of social work practice, initiatives to improve the inclusion of fathers, and the evidence for the effectiveness of interventions.

In this article, the term 'fathers' is used inclusively, recognizing that there are a range of relationships to children to which the term could apply – biological fathers, adoptive fathers, stepfathers, and other less formalized social father roles. It is important to begin this article by acknowledging diversity, since as well as a range of different kinds of relationship to children, there is also a range of fathering practices and the meaning of fatherhood status is not fixed but will vary between and within cultures and locations.

Social workers can encounter men as fathers in many different roles. Child and family settings range from universal services through to casework where children are at risk of significant harm. Obviously, fathers can also have other social needs and therefore fathering can be relevant to many other social work issues such as, for example, substance misuse, mental health, offending, and disability.

There are several reasons why it is important to work with fathers. These include sharing the responsibility for children's welfare, rather than putting undue pressure on mothers, and respecting children's rights to a relationship with men who are significant to them. There is evidence from cohort studies of the importance of fathers to children's development. For example, Flouri and Buchanan's (2002) analysis of the UK National Child Development Study found that father involvement at age 16 predicted diminished psychological distress at age 33 for women. Lamb (2010), in summarizing the greatly expanded field of research on father influence, notes that the effects mothers and fathers have on children are more similar than they are different. Fathers' individual characteristics are less important in determining the influence on child development than their quality of relationship with their children. The amount of time fathers spend with children is probably less important than the quality of that contact and how it is perceived by all parties. Finally, fathers' relationships with their partners and ex-partners are also important for positive paternal influences.

There is very limited evidence that including fathers as well as mothers leads to more positive outcomes for family services. The meta-analysis of parent training evaluations by Lundahl et al. (2008) found that programs involving both mothers and fathers achieved more desirable parenting practices and more positive changes in children's behavior than programs involving only mothers. Also, Bellamy's (2009) study of child welfare cases from the US National Survey of Child and Adolescent Well-Being found that the involvement of a noncustodial parent, which was most often a biological father, was associated with reduced likelihood of children being placed into out-of-home care.

The Social and Cultural Context of Fathering

A thorough overview of the contemporary social and cultural context of fathering, with salient connections to social work, is provided by Featherstone (2009). Here, I simply summarize a few important issues. There is, of course, substantial international and intranational variation in the context of fatherhood. Differences in local economy and social class, ethnic culture, and religion are just some of the variables which can influence fathers' involvement in family life. A dominant new discourse at least in Western countries is that of intimate fatherhood (Dermott, 2008) wherein fathers are expected to forge an emotional bond with their children. This is clearly a change from previous generations where financial provision was seen as paramount. However, as Miller's (2011) British research shows, despite fathers' increasing involvement in hands-on care, it is usually mothers who continue to carry the load of '24/7 caring and thinking responsibility' (p. 171). Many European countries – and especially Nordic ones – have moved social policy in the direction of supporting work–family balance and the greater involvement of fathers in child care, although there is some way to go and tensions remain (O'Brien and Moss, 2010).

Social workers tend to intervene where there are social problems. It is inevitable, therefore, that although the fathers encountered by social workers can be resources for the care and nurturing of children, the behavior of some fathers puts women and children at risk. This problematic behavior also

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28032-X

indicates these men's own psychosocial vulnerability (Featherstone, 2009). In many countries, social workers have an important role in protecting children from maltreatment, so it is inevitable that some of their contact with fathers will be in this context. There is a large body of research on gender in relation to child maltreatment and a review of this evidence is beyond the scope of this article. Here, I simply note that the latest UK prevalence study (Radford et al., 2011) found an overall gender symmetry in the maltreatment of children under 18, but men were more likely than women to perpetrate *severe* maltreatment of children in this age range. Men were also more likely than women to maltreat young people aged 18–24. When it came to different kinds of abuse, men were more implicated in severe physical abuse and in all kinds of sexual abuse. The research by Berger et al. (2009) using the US Fragile Families and Child Wellbeing Study found that children were more likely to come into contact with child protection services in families with men not biologically related to the children and families with men who are not romantically involved with the children's mothers. Bellamy's (2009) study of US child welfare cases found that caseworkers perceived nonparental males (i.e., men who were neither biological, step-, or adoptive fathers) in households to pose a greater risk to children than parental males. Children living with nonparental males were also significantly more likely to come into out-of-home care. However, the presence of a nonparental adult male in the household was not associated with future maltreatment reports. This could be, as Bellamy acknowledges, because men putting children most at risk have left the family by the time of the later survey wave. However, as Dubowitz (2009) notes, it might suggest unhelpful practitioner stereotyping of nonparental males. This leads us into the next subsection of critiques of current social work practice.

Social Work Approaches to Fathering

The rest of the article provides an overview of social work approaches to fathering, starting with a summary of critiques of current practice and then moving on to more positive terrain with an overview of attempts to improve the engagement of fathers and the evidence base on the effectiveness of interventions.

Critiques of Current Practice

There is a broad consensus that current social work practitioners tend not to do a very good job of engaging with fathers. Initial engagement is one aspect of the social work process, but fathers also need to enroll in social work interventions and then stay involved (Gordon et al., 2012).

There are problems with men's involvement in all kinds of family services, but perhaps the difficulties are most acute in child protection, where the stakes are especially high. The barriers are many, and concern the attitudes of mothers and the reluctance of fathers themselves in many cases, as well as the roles of practitioners (Maxwell et al., 2012). It is important to understand the different levels on which barriers to father involvement operate. Gordon et al. (2012) provide a useful review and ecological analysis which separates out individual, family, service provider, program, community, and policy levels. Although Gordon et al. see the evidence base as slender, in fact a body of qualitative research with practitioners has emerged in recent years, albeit some of this research has not been published in journals but in 'gray' literature or in student dissertations. One important theme from qualitative research has been practitioner culture, which acts against the involvement of fathers in fairly complex ways. Scourfield's (2003) ethnographic research from the United Kingdom described a mixture of gendered discourses in social work office culture. Some of these discourses were in tension with each other, but the combined effect was to make the engagement of men much less likely than the more familiar practice of working with mothers. Strega et al. (2008) provide a relatively rare quantitative picture from their mixed method research in Canada. They found that social workers deemed fathers to be irrelevant to mothers and children in 50% of cases and only 50% of those fathers who were seen as an asset to children were contacted.

Where the evidence base on barriers undoubtedly is very thin is in relation to fathers' own accounts of social work contact (or the lack of it). One example is the Family Rights Group, Fathers Matter research (Ashley et al., 2006), in which fathers spoke of seeing workers as firmly pro-women and anti-men. In another study of men whose children were in the care of the state, Dominelli et al. (2011) describe fathers' own accounts as transcending the good father–bad father binary which tends to be dominant in practice (Brandon et al., 2009).

Initiatives to Improve the Engagement of Fathers

As was noted at the beginning of this article, there is a range of services for fathers from those which are universal for parents in a locality, through to highly targeted interventions for fathers whose behavior is putting children at risk. Most common would be for fathers to be involved in services for parents – i.e., mothers and/or fathers – such as informal support via a family center or attendance at a parent training course. Less common would be specific services for fathers, although there are many examples of father-only services which have been designed to combat their reluctance to come to mainstream settings (Ghate et al., 2000).

As an example of within-country variation, a recent survey I undertook on interventions with fathers across the United Kingdom (see Scourfield, 2013) found there to be large numbers of men attending very informal 'stay and play' sessions – some with mothers and some for fathers only, as well as healthy numbers of men attending universal parenting courses alongside mothers. There were also examples of targeted interventions with healthy numbers of men attending, courses in prison and programs for men whose behavior was putting children at risk. Most practitioners were offering one-off local groups, set up perhaps by individuals with a particular interest in fathers. Many of these were unstructured social support groups.

Magill-Evans et al. (2006) conducted a systematic review of interventions for fathers of young children. Although their interest was in health care and health promotion more than social work, the diversity of approaches they describe indicates the creative range of interventions which is also

found in social care. They found studies of discussion groups, infant massage, kangaroo care (infant held skin-to-skin), observation and modeling of interactions with infants, participation in a preschool program, and parent training programs. McAllister et al. (2012) took a consciously international approach to their 'critical review of best practice' and identified 35 programs which have promoted or facilitated the involvement of men with children up to 8 years of age. Some of these (e.g., Triple P parenting courses) are used extensively in many different countries, whereas others are country-specific. They found little published evidence of projects in the Global South engaging with men as fathers, although there were several examples of interventions with men (e.g., on violence prevention or sexual health), from which lessons could be learned for work with fathers.

In addition to these dedicated interventions for fathers, some men-only and some alongside mothers, there have also been attempts to improve mainstream social work with fathers, in response to the criticisms noted above. For example, the Fathers Matter projects instigated by the Family Rights Group in the United Kingdom (see, e.g., Ashley et al., 2006) have tackled statutory social work services for children and families and have been followed by a Fatherhood Institute initiative to improve the engagement of fathers in child safeguarding in England.

The politics of social work with men can be fraught (Featherstone et al., 2007), with some opposing views which seem difficult to reconcile. For example, some feminist practitioners and academics emphasize the risk to women and children that can result from men's continued involvement with children after domestic abuse (e.g., Harne, 2011). Men's rights advocates, in contrast, such as the UK organization Families Need Fathers (see http://www.fnf.org.uk/), tend to argue for keeping biological fathers involved with children's lives in almost every case. Whereas some have tried to engage violent men in behavior change through their relationships with their children, other practitioners are unhappy that such approaches do not tackle violence against women in a systematic way (Featherstone and Fraser, 2012).

Evidence of Effectiveness

The general conclusion of McAllister et al. (2012) after reviewing the international evidence on social interventions with fathers is that there is little robust evidence on outcomes. Bronte-Tinkew et al. (2007) similarly note from their review of interventions in Western countries that most studies have small sample sizes, there are few experimental studies, and few programs found to be effective have been replicated. There is a large body of evidence on the effectiveness of parenting programs, but McAllister et al. (2012) note that there is a tendency not to disaggregate findings by sex of parent.

There are some findings about parent training programs which paint an optimistic picture for father engagement. As noted earlier, Lundahl et al. (2008) have observed that programs involving fathers as well as mothers are more effective than those for mothers only. However, there is also some evidence that fathers gain less from these interventions than mothers. For example, Nowak and Heinrichs's (2008) meta-analysis of studies of Triple P, the program with the strongest international evidence base, found fathers reporting lower levels of improvement than mothers or teachers for parenting, parental well-being, and child problems. Generally, attendance at parent training is much lower for men than for women. The study by Lindsay et al. (2011) of parents attending one of five evidence-based parenting programs in England – data on gender were available for 6095 parents – found that 15% of parents attending programs were men.

Magill-Evans et al. (2006) considered interventions for parents where there were separate outcomes reported for fathers and also interventions for fathers only. They were reasonably optimistic about outcomes, noting improvement in fathers' interactions with children and perceptions of children. However, they found no evidence of impact on child development and it should be acknowledged that some of the studies they reviewed had very small samples indeed and some had no comparison group, randomized or otherwise. Philip and O'Brien (2012) recently reviewed the evidence on outcomes of interventions for fathers after separation and divorce. Like Magill-Evans et al. (2006), they included interventions for both parents as well as those for fathers only and the review encompassed a range of study designs. Most studies did not disaggregate results by sex of parent. Some positive effects were reported, however. Parental conflict reduced in 11 of the 14 interventions and in half of the interventions, there were improvements in the co-parental relationship and in children's internalization of problems (i.e., sadness and low affect). As with the review by Magill-Evans et al. (2006), it should be noted that Philip and O'Brien (2012) did not limit their review to the most robust evaluations.

A rare example of a robust evaluation is the study by Cowan et al. (2009). Couples ($n = 289$) were randomly allocated to one of three interventions: a 16-week group program for couples, the same 16-week group program for fathers only, and a one-off information session. The group interventions were seen as preventative, so high-risk families were not included. Cowan et al. describe (p. 669) the group program, which was the same for couples as for fathers only, as occupying the middle ground of the continuum between open-ended group theory and psycho-educational teaching of specific skills. Couples in the two-group programs had better outcomes than those who only had a single meeting, in terms of father engagement with children, couple's relationship quality, and children's behavior. More consistent and longer-term effects were found in those who attended the couple's group than in those where only the fathers attended. This might suggest the importance of involving fathers alongside mothers in parents' or couples' interventions where possible. Practitioners work hard to do this, but others respond to the difficulty of enrolling men in parenting interventions by setting up modified versions for fathers only or by developing a new program from scratch which they think will appeal to fathers (Scourfield, 2013). Although some criticism has been leveled at the most widely used parenting programs for not culturally adapting to the need of different ethnic communities and therefore being less successful in recruiting minorities, it should be noted that two-thirds of families taking part in the Cowan et al. (2009) study were Mexican-American (the rest were European-American).

There is very little evidence of the effectiveness of interventions with fathers to prevent child maltreatment. The systematic review by Smith et al. (2012) unearthed 15 studies, but only two of these reported father-specific outcomes. Most of the interventions they identified addressed parenting function and capacity. All except two were mostly attended by women or there was little follow-up data on men. Most of the studies only used pre–post testing of those who received the intervention, with no comparison group. Some of these limitations are beginning to sound fairly familiar.

Addressing other problem behaviors as well as parenting may hold some promise for work with fathers. For example, in the study by Lam et al. (2009), 30 fathers with alcohol problems were randomly allocated to one of three different intervention approaches: behavioral couples therapy; parent skills with behavioral couples therapy; and traditional individual-based treatment for substance misuse. Parent training with behavioral couples therapy was the approach which resulted in the greatest change in contact with child protection services, albeit with a small to medium effect size. Lam et al. acknowledge a larger study is needed to provide stronger evidence on these approaches.

Although there is a lack of robust evidence on the effectiveness of interventions with fathers, process evaluations which describe the theoretical basis of interventions and mechanisms to effect change are also useful. There are some examples of such work on interesting interventions – for example, Scott and Crooks (2007) on 'Caring Dads,' a program for men who are putting their children at risk, and McGuire (2009) on 'Family Man' a prison-based program to enhance father involvement. The next stage with such programs is to measure outcomes in a comparative study design.

Finally, it is worth noting that there is also very little evidence about initiatives to improve the engagement of men in mainstream services. The little work that has been published is summarized here. English et al. (2009) put in place a half-day training course for all practitioners in child welfare services in one US state, as well as optional additional training modules which were taken up by some staff. Pre–post testing suggested some gains in father engagement as evidenced by agency self-assessment and case file review. Scourfield et al. (2012) developed a two-day training course on the initial engagement of fathers for child protection social workers in South Wales which included a day of skills training, via an introduction to motivational interviewing. They found a significant increase in trainees' self-efficacy for work with fathers and also in their self-reported engagement of some fathers on caseloads. There was a large self-reported increase in the engagement of nonresidential fathers and a smaller but significant increase in the engagement of nonrisky men living with children. There was, however, no change in the engagement of men who are putting children at risk. Both studies, English et al. (2009) and Scourfield et al. (2012), only used pre–post testing and no comparison group.

Conclusion

There has been a modest flourishing of practice developments in this new social work field in recent years. These developments do not always come from those who call themselves social workers, but the scope of this article has included all social interventions and a broad definition of 'social work' has been used. The UK survey I have undertaken (see Scourfield, 2013) shows great practitioner creativity, especially in universal family support programs. Attempts to get men involved with social or parenting support have included the use of activities traditionally associated with masculinity, such as sport and Lego (a building toy), and also less traditional activities such as art and cooking. It seems, however, that many of these creative interventions may rely on the dedication of individual practitioners. Although in some areas of practice there has been support at a policy level for more engagement of fathers – for example, the Sure Start early childhood initiative in the United Kingdom – there is much work to be done in getting the importance of work with fathers explicitly recognized in policies. Unless major public and third-sector organizations make father work a policy priority, it is likely to proceed in a piecemeal fashion and remain on the margins of social work.

There will always be debate about appropriate methods in this field. It has already been noted that the politics of fatherhood are controversial. Practitioners and commentators also disagree about whether or not it is right to use traditional aspects of masculinity as a way to engaging men in services (see Featherstone et al., 2007). Most would see the sense of some pragmatism in this regard and there is room for the kind of experimentation mentioned earlier. Given the diversity of fathers and fathering, a range of different intervention approaches is needed. However, it is also important to establish the effectiveness of interventions, even if those that are found to be effective should not be regarded as universally applicable. It is important now that we add to the existing process evaluations and pre–post testing of intervention participants by setting up experimental and quasiexperimental studies which compare the outcomes of the intervention with outcomes for normal services. There is particular need perhaps for robust evaluation of those interventions where the stakes are highest, namely those for fathers whose behavior is putting children at risk.

I end this article by reproducing the 10 'characteristics of effective fatherhood programs' identified by Bronte-Tinkew et al. (2007: pp. 10–12) on the basis of their review of evaluated programs in Western countries. In identifying these characteristics, these authors are drawing on the wider evidence base on effective practice in social interventions. Effective programs are those which incorporated teaching methods and materials appropriate for fathers and the cultures of the populations served; selected teachers or leaders who believed in the program they were implementing and then provided them with training; had a higher staff–participant ratio; used targeted curricula; used theoretical approaches that have been effective in influencing parenting behaviors in other contexts; employed a variety of teaching methods designed to focus on the fathers as individuals, and thereby personalized the information; lasted a sufficient amount of time to complete important core activities adequately; had staff who engaged in one-on-one relationships with fathers; encouraged the use of an incentive to fathers and/or their families; and replicated their curricula with fidelity.

These criteria do not fit all intervention approaches. They do not, for example, sit comfortably with father-led community development approaches. However, they are a useful starting point for discussion about what makes an effective approach to social work with fathers.

Fear Conditioning: Overview

Herta Flor, Heidelberg University, Mannheim, Germany
Niels Birbaumer, University of Tübingen, Tübingen, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Fear conditioning refers to the pairing of an initially neutral stimulus with an aversive fear-eliciting stimulus. The conditioned fear response is described in terms of subjective, behavioral, and physiological responses. The psychobiological basis of fear conditioning in animals has been well established, and the amygdala has been identified as a central structure. Genetic variables as well as cognitive factors also contribute to fear conditioning. The significance of fear conditioning for the understanding of many mental disorders has been investigated with a focus on extinction learning and the consolidation and reconsolidation of extinguished memories.

Basic Terms

The pairing of an initially neutral stimulus (the conditioned stimulus, CS) with a biologically relevant stimulus (the unconditioned stimulus, US) comes to elicit a response (conditioned response, CR) that is usually, but not always, similar to the response previously associated with the unconditioned stimulus (the unconditioned response, UR). In fear conditioning, the US is an aversive fear-eliciting stimulus such as painful electric shock or loud noise, the CS is a neutral tone or light stimulus. The UR and the CR consist of changes on the subjective, behavioral and physiological level and include (in humans) enhanced subjective fear and (in animals) freezing, but also changes in heart rate and skin conductance, the release of stress hormones, altered pain sensitivity, and startle reflex potentiation.

The development of the CR is based on the formation of an association between a neutral stimulus and a stimulus with innate biological significance that then predicts the US (Rescorla, 1988). Most studies involving fear conditioning have used cue conditioning, i.e., discrete CSs such as tones or graphic displays were presented. Usually delay conditioning, where the CS overlaps with and often terminates with the US, has been used rather than trace conditioning, where the CS and the US are separated in time. In addition to cue conditioning, context conditioning has been studied, where the CS is not a discrete cue but an internal or external context (Maren et al., 2013) such as a room or a certain mood state (**Figure 1**).

Fear can be viewed as a specific reaction to threatening stimuli. It can turn into an anxiety disorder when the fear becomes disproportionate to the stimulus that elicits it or when fear is experienced in inappropriate situations. Cue conditioning is thought to elicit fear, whereas context conditioning has been associated with anxiety. Due to the unpredictable nature of the US, anxiety rather than fear seems to be the main behavioral correlate.

Mechanisms of Fear Conditioning in Animals

The psychobiological basis of fear conditioning in animals, especially rodents, has been well established (LeDoux, 2000, 2014). When a tone is used as CS and electric shock as US, the auditory CS reaches the lateral nucleus of the amygdala from the thalamus or the cortex, probably, depending on the complexity of the CS. When contextual stimuli are employed as CS, the hippocampus is also involved and transmits the signal to the basolateral and the accessory basolateral nucleus of the amygdala. The nociceptive US also reaches the lateral nucleus of the amygdala via thalamic and cortical pathways. Conditioning seems to require an intact lateral nucleus of the amygdala when cue conditioning is involved and an intact basolateral and accessory basolateral nucleus when context conditioning is involved. The central nucleus of the amygdala receives input from the lateral and basolateral nuclei, and it projects to brainstem nuclei that initiate the expression of peripheral fear responses. While the lateral or basolateral nuclei are thus important for the acquisition of the CR, the central nucleus is essential for the expression of the CR (see **Figure 2**). Further processes that occur are changes in synaptic strength as well as altered gene expression and protein synthesis, which results in long-term memories (Johansen et al., 2011).

The initial site of plasticity seems to be the lateral nucleus of the amygdala involving both excitatory and inhibitory circuits (Ehrlich et al., 2009); however, thalamic and cortical reorganization has also been shown during fear conditioning (cf Marek et al., 2013). The amygdala plays an important role in the formation of the memory trace, but memory traces are also established elsewhere, especially for long-term memory storage. If the amygdala is inactivated during fear conditioning, no CR is formed. If the inactivation occurs after conditioning, then the memory trace is not abolished (Pape and Pare, 2010).

Fear Conditioning in Humans

In humans, the role of the amygdala is less clear than in animals. In contrast to rodents, humans possess a much larger prefrontal cortex and it is likely that it takes over some of the functions that are related to the amygdala in rodents. Damage to the amygdala in humans, has, however, also been related to deficits in fear conditioning, whereas lesions in the hippocampus have been shown to interfere with declarative learning

Figure 1 Cued fear conditioning as depicted in the first row involves discrete neutral cues such as circles or diamonds that serve as conditioned stimuli (CS) and unconditioned stimuli (US) such as painful electrical stimulation. The CS precedes the US in a lawful manner and usually coterminates with the US. In differential fear conditioning, one CS (the CS+) is paired with the US and serves as danger signal, whereas another CS (the CS−) is never paired with the US and serves as safety signal. In contextual cue conditioning, a context such as a room serves as CS and the US is unpredictable because there is no fixed time between the onset of the CS and the US.

and contextual fear conditioning (cf Bechara et al., 1995). Most studies using functional magnetic resonance imaging and differential conditioning paradigms in humans found amygdala activation, which was positively correlated with activations in the primary sensory cortices, the prefrontal cortex, and the thalamus (cf Sehlmeyer et al., 2009). The notion that a direct pathway from the thalamus to the amygdala also exists in humans was supported by showing that activation of the right amygdala in a masked conditioning paradigm was associated with activity in the superior colliculus and pulvinar, but not with activity at cortical sites (Morris et al., 1999). In addition to the amygdala, the acquisition of a fear response creates activation in the cingulate gyrus and the premotor cortex. Activation of the insulae has also been reported when painful stimuli were used as US. When trace or context conditioning was employed, activation in the hippocampus in addition to activation in the amygdala and cortical areas was noted (Maren et al., 2013).

Based on the observation that not all stimuli are equally easy to condition, Seligman (1971) suggested that phylogenetically relevant stimuli such as snakes or spiders might serve as 'prepared stimuli' and be more conditionable than others. Subsequently, Öhman (for a review see Öhman et al., 2000) has shown that conditioned skin conductance responses to a prepared CS such as an angry face or a picture of a snake persist for a longer time (even when the presentation is masked) than when a neutral stimulus such as a picture of a mushroom is used as CS and combined with electric shock as US. Moreover, masked presentations of these stimuli also lead to the acquisition of conditioned responses suggesting that unconscious learning of these stimulus associations is possible.

More recent accounts of fear conditioning have emphasized the role of extinction and extinction memory (see below), as well as cognitive variables of fear including expectancy and prediction error. Prediction error refers to the circumstance that an obtained outcome differs from a predicted outcome, in fear learning, for example, the probability of the occurrence or nonoccurrence of the aversive US neurons in several brain structures, including the amygdala, code prediction, and violations of prediction. Computational models of fear conditioning have shown that prediction error coding is a fundamental principle of fear learning (McNally et al., 2011).

Extinction and Extinction Memory

Extinction and extinction memory have increasingly become a focus of research, since these processes are thought to be seminal for the understanding of learning but also of anxiety disorders. Extinction occurs when the CS is repeatedly presented without the US, leading to a gradual reduction of the conditioned fear response. While pavlovian fear conditioning may be evolutionarily adaptive and should thus be strong in all persons, extinction of fear is greatly context-dependent and may show larger interindividual variability. Extinction is not only the inhibition of fear, but also a new learning process, where a new association between the CS and the absence of the US is formed (Schiller and Delgado, 2010). Extinction has been separated in early and late stages, with the late stage (after 6 h) being related to protein synthesis, and thus more stable memories. The infralimbic cortex in rodents and its medial prefrontal counterpart in humans play a major role in extinction; hypoactivation or reduced cortical thickness in these

Figure 2 Fear stimuli proceed from sense receptor systems to the sensory cortex and/or sensory thalamus and then to the amygdala. There are three important connections efferent to the amygdala: (a) a projection from the central amygdala to the lateral hypothalamic area that mediates the autonomic components of the emotional response; (b) projections to the midbrain central gray region mediates defensive freezing and escape behavior and (c) a direct projection to the nucleus reticularis pontis caudalis modulates the startle reflex. Based on Bradley, M.M., Lang, P., 2000. Measuring emotion: behavior, feeling and physiology. In: Lane, R.D., Nadel, L. (Eds.), Cognitive Neuroscience of Emotion. Oxford University Press, New York.

regions interferes with extinction, and stress-induced impairments of extinction are related to atrophy and a loss of GABAergic inhibition in the infralimbic cortex (cf Akirav and Maroun, 2007). There is also evidence that the prelimbic cortex (or dorsal anterior cingulate in humans) is hyperactive when extinction is deficient. The prefrontal cortex inhibits fear via inhibition of the amygdala, which has specialized extinction encoding neurons, and its disruption may be important for the lack of fear extinction such as in post-traumatic stress disorder (PTSD). Extinction is dependent on the *N*-methyl-D-aspartate (NMDA) receptor. Several phenomena that disrupt extinction have been described. Recovery of fear refers to the process that fear may be spontaneously reactivated and extinction may be forgotten with the passage of time. Renewal refers to the fact that an extinguished memory of fear becomes active when a change of context occurs (Vervliet et al., 2013). Finally, reinstatement refers to the return of fear when the unconditioned stimulus is presented again. The hippocampus plays an important role in extinction and extinction memory related to the fact that extinction but not acquisition is context-dependent (Bouton et al., 2006). Extinction can be facilitated by the use of pharmacological enhancers. For example, the partial NMDA receptor antagonist D-cycloserine has been employed to speed up the extinction process in both animals and humans; however, the result has been equivocal. Recent accounts of extinction have also emphasized the similarity of extinction learning and reward processing, and this may led to new insights about the mechanisms of the extinction process.

Learning results in the consolidation of fear memories, but these memories can become labile when they are recalled and can then be enhanced or diminished in this process of 'reconsolidation.' Reactivation can occur by the presentation of a memory associated environmental cue (such as a fear conditioned CS). Monfils et al. (2009) and Schiller et al. (2010) have shown that a previously conditioned CS presented early

Figure 3 Design of the study that used the lability of the fear trace in the reconsolidation window by administering propanolol before the memory was reactivated by the presentation of a conditioned stimulus that reactivated the fear. When later extinction and reinstatement were tested, the disruption of fear reconsolidation by propanolol led to better extinction and less reinstatement. Based on Kindt, M., Soeter, M., Vervliet, B., 2009. Beyond extinction: erasing human fear responses and preventing the return of fear. Nature Neuroscience 12, 256–258.

but not late (>6 h) after acquisition and prior to extinction can eliminate the spontaneous recovery of fear, reinstatement, renewal, and fast reacquisition. The idea is that the CS presentation reactivates the memory and makes the fear-memory trace labile in a reconsolidation window that lasts up to 6 h, so that it can easily be overwritten by extinction. This could have important implications for the treatment of fear and anxiety, because one could make use of this reconsolidation window to develop better treatments of anxiety disorders. For example, Kindt et al. (2009) showed that the use of propranolol shortly before the reactivation of a fear memory erased the later expression of fear and also prevented its reactivation (see Figure 3).

Genetic and Epigenetic Factors

Genetic factors seem to play a role in the development in anxiety disorders in humans. Familial studies, twin studies, and adoption studies show genetic variances of 20–40%. The same was found for fear conditioning. Fear conditioning ability and predisposition to learn fear responses were extensively studied in animals. In rodents, fear processes or anxiety measured in the open field test or avoidance conditioning have revealed a strong genetic basis explaining most of the interindividual variance. However, the genes responsible for that trait have only partially been identified. Important genes that modulate fear conditioning involve the serotonin transporter (5HTT) and the catechol-*O*-methyltransferase (COMT) gene. Moreover, genes involved in the regulation of the hypothalamus–pituitary–adrenal axis such as the glucocorticoid receptor gene or the corticotropin-releasing hormone genes, but also the dopamine transporter (DAT1) and the pituitary adenylate cyclase 1 receptor (ADCYAP1R1) genes have been implicated (Lonsdorf and Kalisch, 2011). Controversial data exist for the brain-derived neurotrophic factor (BDNF) gene. There is also mounting evidence that epigenetic mechanisms such as DNA methylation and histone modification contribute to fear conditioning (Zovkic and Sweatt, 2013). For example, histone acetylation and DNA methylation were found to be crucial for fear memory consolidation and synaptic plasticity in the lateral amygdala. Dias and Ressler (2014) showed that prenatal fear conditioning odors led to enhanced startle responding, neuroanatomical changes, and hypomethylation of an odor receptor encoding gene in the offspring of the trained animals, thus explaining transgenerational effects in fear learning.

Significance of Fear Conditioning for the Understanding of Anxiety Disorders

Although classical fear conditioning has been implicated as an important mechanism in the development of most anxiety disorders, there are few studies that support the etiological significance of fear conditioning. Retrospective data from either adult or child patients or the parents of children with specific phobias revealed that about 40–75% of the subjects or the parents could recall a traumatic event (e.g., Menzies and Clarke, 1993); a substantial number of the remaining subjects experienced vicarious conditioning or had been verbally informed about potential dangers related to the feared object. In evaluating these data, it must be kept in mind that all these reports are retrospective and that fear conditioning may be nondeclarative and therefore not be accessible to conscious recollection. Of greater relevance are, therefore, studies that examine fear conditioning in clinical groups or analogue samples. In social phobics, several studies used differential conditioning with faces as CS and aversive odor or shock as US and found either preexisting abnormalities or abnormal fear learning. In persons with psychopathy and antisocial personality disorder, disturbed fear conditioning seems to be present with a concomitant complete absence of orbitofrontal, insular, and cingulate activation during fear conditioning (e.g., Birbaumer et al., 2000). This absence of associative learning with respect to the aversive consequences of a stimulus might be the basis of the antisocial and often criminal behavior of these persons. In PTSD, higher conditionability as evident in enhanced and more difficult to extinguish fear responses has been observed. There is some evidence that delayed extinction of fear before

the disorder is predictive of the onset of PTSD later on. In addition, deficient context conditioning seems to co-occur with enhanced cue conditioning, lack of fear extinction, and excessive generalization (Flor and Nees, 2014; Milad and Quirk, 2012), and this dissociation of cue and context conditioning may be a crucial factor in the maintenance of aversive and disruptive trauma memories. More recently, pharmacological enhancers of extinction have gained much attention based on the increasing evidence of the molecular mechanisms involved in fear acquisition and extinction circuits such as the NMDA receptor, opioids, or dopamine (Fitzgerald et al., 2014).

Future Perspectives

Future research must focus on the elucidation of the neuronal correlates of fear conditioning in healthy humans and patients. It is not clear to what extent the amygdala plays the same role in fear conditioning in humans as it does in rodents. Furthermore, the role of awareness of the CS and the CS–US relationship has become more important with the view that the prediction of aversive events and the computation of prediction error is a crucial characteristic of fear learning. The advent of new methods such as optogenetics to specifically manipulate neural cell populations with high temporal and spatial precision, permits the elucidation of fear circuit activity in great detail (Johansen et al., 2012). The importance of fear conditioning for the understanding of anxiety disorders needs to be explored using paradigms that involve longitudinal measurements. Finally, the role of cognitive and genetic variables and their relationship to fear conditioning needs to be further explored.

Fear of Crime

Jodi Lane, University of Florida, Gainesville, FL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Fear of crime is more common than victimization and is important because it can lead to stress and behavioral precautions that impinge on quality of life. This article discusses definitions of fear as an emotional reaction (not a cognitive one) and enumerates how scholars have worked to better their fear measurements over time. The article also discusses the personal characteristics that predict fear and describes the theoretical ideas developed to explain it, including vulnerability (especially for women and the elderly), neighborhood factors (subcultural diversity, disorder, and community concern), and indirect victimization. Finally, we briefly discuss current and emerging trends in research.

Fear of Crime: Importance and Definitions

When people think about crime, they often consider its causes – or why people do it – and the consequences for others involved in the immediate criminal event, including victims and witnesses. Yet, crime has broader consequences beyond the people directly affected by or involved in specific incidents. One consequence is fear of becoming a victim, which is much more common among the population than victimization itself (Warr, 2000). While very few people report being victimized by violent crime (fewer than 3%) or property crime (about 14%) (Truman and Planty, 2012), a recent Gallup poll found that 38% of Americans were afraid to walk in the area around their home at night (Gallup, 2011). Research in other countries also finds that fear of crime is high compared to one's risk of personal victimization (European Crime Prevention Network, 2004).

Fear of crime is an important social issue generally and to policy makers because it affects quality of life and can lead to regular anxiety and behavioral changes, including avoiding specific areas, restricting daily activities, fortifying one's home, and carrying weapons to protect oneself (Ferraro, 1995; Warr, 1985). At the extremes, it might lead someone to do something passive but life altering, like refuse to leave his or her home, or active, like join a gang or commit peremptory attacks on others to prevent personal victimization (Lane and Fox, 2012).

As discussed in this article, over time, scholars have been inconsistent in how they measure, and therefore operationally define, fear of crime, but in the last 20 or so years, researchers have agreed that fear refers to an emotional reaction (not a thought process). For example, Ferraro (1995: p. 23) defined fear of crime as "an emotional response of dread or anxiety to crime or symbols that a person associates with crime" (see also Ferraro and LaGrange, 1987). Warr (2000: p. 453) further clarified the definition as "an emotion, a feeling of alarm or dread caused by an awareness or expectation of danger." While Farrall et al. (2009) agree that fear can be an emotion with an associated physical response, they argue that it is rare for people to have such an intense feeling. Rather, they argue that most people respond to crime emotionally in terms of worry about something happening to them now or in the future, and they note that it is important for researchers to measure the regularity and intensity of emotional reactions to crime.

Changes in Measurement of Fear over Time

Fear of crime has been measured in a variety of ways, depending on the study and its purpose. Before the 1980s, it was very common for researchers to measure fear of crime with one of two questions. The first, "How safe do you feel or would you feel being out alone in your neighborhood at night? (or during the day)," was designed for use in the National Crime Survey, now called the National Crime Victimization Survey. The second, "Is there any area right around here–that is, within a mile–where you would be afraid to walk alone at night," was developed for the General Social Survey (GSS) (Ferraro, 1995). In the 1980s, key fear-of-crime experts, including Ken Ferraro, Randy LaGrange, and Mark Warr, began criticizing these measures because they (1) confounded perceived risk of victimization, a cognitive assessment, with fear of crime, an emotional reaction; (2) did not mention the word crime; (3) did not distinguish among fears of different crimes (homicide, assault, burglary, etc.); and (4) asked about fear in hypothetical situations ('Would you?') rather than in everyday ones (Ferraro and LaGrange, 1987; LaGrange and Ferraro, 1987; Warr, 1984; Warr and Stafford, 1983; see also Farrall et al., 1997). While the GSS still uses its question and Gallup (2011) still uses a variation of the GSS question, "Is there any area near where you live–that is, within a mile–where you would be afraid to walk alone at night?," most scholarly studies in the last 20 years have focused on (1) measuring both perceived risk and fear of crime, (2) measuring perceived risk and fear of multiple offenses, and (3) ensuring that words that specify fear are included in the questions (e.g., 'afraid,' 'worry,' or 'safety'). In addition, some scholars have recently added more specificity to measures by arguing that fear may vary not only based on types of offenses but also based on types of offenders. Specifically, Lane and Meeker have argued that perpetrator characteristics can add another layer to our understanding of fear, and researchers in the last decade have conducted studies examining fear of gang members, terrorists, and strangers versus known offenders, for example (see Lane and Meeker, 2000, 2003b, 2003c, 2004; Nellis, 2009a, 2009b; Wilcox et al., 2006).

Changes in Research Focus over Time

Personal Characteristics

Much of the early research on fear of crime focused on measuring the prevalence of fear and understanding the characteristics of people who were afraid. Early studies, using the general but problematic questions, showed that victims, minorities, and people living in urban (and especially lower income) areas were more afraid. In addition, results also indicated that women and the elderly were more afraid than men and younger people, even though they faced less actual risk of victimization (see, e.g., Baumer, 1978; Garofalo and Laub, 1978; Skogan and Maxfield, 1981; Warr, 1994, for a review). It made intuitive sense to researchers that people who lived in urban and low-income areas, often minorities, would be more afraid of crime, because crime was more common in those areas. Yet, early researchers were puzzled by the fact that women and the elderly were expressing more fear than males and young people, which led them to focus their work on understanding and explaining causes of crime-related fear other than objective risk of victimization. One approach, as mentioned here, was to improve the measurement of fear of crime, first by separating perceived risk from fear and by examining fear of specific offenses (e.g., LaGrange and Ferraro, 1987; Warr, 1984, 1985; Warr and Stafford, 1983). Interestingly, many of the studies that have examined fear of specific offenses in the last 30 years or so have continued to find that women were more afraid than men; yet, in contrast, they also found that younger people, not older ones, were more afraid, lending more support to expressed concern over the value of earlier measures (see, e.g., Ferraro, 1995, 1996; Lane and Meeker, 2003b; Warr, 1994, for a review). Other approaches were theoretical, and studies focused on finding factors other than demographic characteristics that could explain fear of crime. The next few sections will discuss the theoretical approaches that emerged over time and the research conducted to examine those theoretical ideas.

Vulnerability

One of the ideas to explain differential fear among people was argued by scholars such as Skogan and Maxfield (1981) and focused on physical and social vulnerability. Skogan and Maxfield (1981) noted that women and the elderly faced more physical vulnerability than males and young people. 'Physical vulnerability' refers to the possibility that they may be less likely to be able to protect themselves if attacked and to be physically injured if they were attacked, due to their generally smaller statures and comparative lack of physical strength. Women as a group tend to be smaller and have less physical power. The elderly have an additional burden of losing their physical strength and ability to move quickly as they age, and many of them live alone, especially women, since men tend to die younger. Skogan and Maxfield (1981) noted that many elderly would have no one to take care of them if they were injured, meaning that they might face being put into institutions if they were severely injured and could not care for themselves. According to Skogan and Maxfield (1981), people who are socially vulnerable, in contrast, are those who live in places where victimization risk is higher, that is, where crime is higher. In the United States, these people are more likely to be minority and poor. Even though many people in these groups may not have yet been victimized and may not be, their daily experiences in their neighborhoods mean that exposure to crime is higher in terms of what they witness and know about, and therefore their crime-related stress is higher.

Theoretical Perspectives on Gender Differences in Fear

Because women are consistently more afraid than men, no matter how fear is measured, some scholars have focused their theoretical arguments on specifically explaining greater fear among women. There are three related but distinct perspectives beyond the simple physical vulnerability argument, and all of them at some level point to feelings or experiences of vulnerability for women (Lane, 2013). The first is "differential socialization," which argues that the reason that women do not feel strong enough to protect themselves from victimization is that "women are socialized to be weak and submissive while men are socialized to be strong and powerful" by their parents and society at large (Lane, 2013: p. 58; see also De Groof, 2008). Hollander (2001) elaborated this argument when she found that her respondents just accepted that women were weaker, even though in reality some women are stronger than some men. She argued that being weak was part of being feminine and being strong and dangerous was considered an important element of masculinity. Interestingly, a recent study in Belgium found that the gender identity mattered more than biological sex did. Specifically, people who were attitudinally and behaviorally more masculine were less afraid than people who were more feminine, regardless of their biological sex (Cops and Pleysier, 2011; see Lane, 2013, for a review).

The second theoretical perspective on women's fear, originally specified by Kenneth Ferraro (1995, 1996), is the "shadow of sexual assault" thesis. Ferraro argued that women are more afraid of crime more generally because they continually worry that nonsexual crimes (e.g., harassment and burglary) can turn into sexual assault. Rape and other offenses served as what Mark Warr (1985: p. 245) called "perceptually contemporaneous offenses," because they were tied together in women's minds. They might be tied, in part, because women have been socialized particularly to fear rape, for example, by their parents who worried about how they dressed or with whom they went out (see Warr, 1984). Some other scholars (e.g., Gordon and Riger, 1989) have argued that fear of rape is a particular predicament that applies only to women. Studies aimed at testing this theoretical idea have consistently found that fear of rape is tied to fear of other crimes for women, and some studies have also found that it predicts fear of other crimes for men, too (Cook and Fox, 2012; Fisher and Sloan, 2003; Hilinski, 2009; Lane and Fox, 2013; Lane et al., 2009; Lane and Meeker, 2003c; May 2001b; Wilcox et al., 2006; see Lane, 2013, for a review).

The third theoretical idea focused on explaining greater fear of crime among women focuses on patriarchy, arguing that men use the threat of rape as a tool purposely to dominate and control women (Brownmiller, 1975). Betsy Stanko, a scholar who now heads the research unit for the London Metropolitan Police, has conducted qualitative research

studies with men and women about their fear of crime. She believes that women's greater fear of crime makes sense, because their 'ordinary experiences' in everyday life show them that they should be afraid (Stanko, 1985: p. 9). She believes that in a male-dominated society, men regularly terrorize women through the threat of physical and sexual harm. She also believes that typical crime statistics do not capture the subtle ways that men victimize women or women's crime experiences with acquaintances or family members, therefore underestimating the criminal victimization that women face (Stanko, 1985; see also Young, 1992). Stanko (1985, 1990) and Esther Madriz (1997) both find problematic the societal expectation that women can protect themselves from men if they just behave appropriately (e.g., dressing conservatively or avoiding certain places or men), because this puts the responsibility for violence against women on the women rather than the male perpetrators who actually commit the violence and hurt them (see Stanko, 1998).

In sum, the vulnerability argument points to either personal or environmental vulnerabilities that lead people to worry that they will become victims of crime, and some scholars believe these explanations easily can explain differential fear levels between women and men. As this section has illustrated, some scholars believe that social vulnerability arises for women because they are treated differently in society. Yet, other research efforts have focused on understanding other environmental factors, such as neighborhood characteristics and media consumption, which can create feelings of social vulnerability and increase fear of crime. Next, we turn to these ideas.

Neighborhood Factors

There are three distinct but connected theoretical ideas about neighborhood or community characteristics that can prompt people to fear crime. These ideas are set in the context of social disorganization theory, a macrolevel theory that posits that crime is more common in areas where residents cannot work together and where poverty, racial and ethnic diversity, and residential mobility are evident (Bursik, 1988; Bursik and Grasmick, 1993; Sampson, 1993; Shaw and McKay, 1972/1942). Fear-of-crime researchers borrowed from this macrolevel theory to create three microlevel theories about neighborhood factors that lead people to fear crime. These perspectives involve subcultural diversity, disorder and incivilities, and community concern and decline.

The first perspective, subcultural diversity, focuses on racial heterogeneity and asserts that people who live near others who look or act differently than they do are afraid because they do not understand the behaviors and mannerisms of those who are different (see Lewis and Salem, 1986; Merry, 1981). That is, they are unsure about how those others will act. Although most scholarly work examining this perspective has considered it in terms of its connections with the other ideas (e.g., disorder and community concern), there is support for this idea. For example, Madriz (1997) found that fear of crime was related to stereotypes about people who were racially and ethnically different, including people from other countries. Lane's (2002) qualitative work on the fear of gangs also showed that people's concern about primarily undocumented immigrants encroaching on their neighborhoods (rather than staying in the barrios) led them to worry about disorder and consequently decline in their neighborhoods, which in turn led them to fear gangs. Quantitative work also supports these findings that racial, ethnic, and cultural heterogeneity matter. For example, studies have shown that concerns about diversity, racial stereotypes, and actual neighborhood racial composition are predictive of fear (e.g., Chiricos et al., 1997b; Lane and Meeker, 2000; Liska et al., 1982; St. John and Heald-Moore, 1996).

The disorder or incivilities perspective asserts that when people see evidence of social (e.g., homelessness, gangs, and kids hanging out) and physical disorder (e.g., trash, unkempt property, graffiti, and bars on windows), they assume that crime is also there and that they are at risk of victimization, leading them to fear crime. Studies have generally shown that perceptions of disorder are important predictors of fear (e.g., Brunton-Smith and Sturgis, 2011; Ferguson and Mindel, 2007; Franklin et al., 2008; Kanan and Pruitt, 2002; LaGrange et al., 1992; Lane and Meeker, 2003a; Lewis and Maxfield, 1980; Robinson et al., 2003; Rountree and Land, 1996; Scarborough et al., 2010; Skogan and Maxfield, 1981; Taylor and Hale, 1986; Taylor, 2001). Fewer have found that objective indicators of disorder matter (Perkins et al., 1990, 1992; Perkins and Taylor, 1996).

The third environmental perspective, community concern, argues that people who are afraid are primarily affected by the fact that their neighborhood is in decline or no longer the way it used to be (Conklin, 1975; Garofalo and Laub, 1978). As Lane (2002) found, this was particularly relevant for long-term residents who had seen their neighborhoods change over time and no longer felt comfortable leaving their doors unlocked or sending children to the park to play alone. Much of the work on community concern links it to disorder, arguing that one of the reasons why disorder is predictive of fear is that it leads people to believe that their community is declining (see Garofalo and Laub, 1978; Skogan, 1990; Skogan and Maxfield, 1981). Lane's (2002) qualitative work showed this connection. Moreover, when quantitative studies examine this theoretical argument, they show support (see Lane and Meeker, 2003a, 2005, 2011; Taylor and Hale, 1986).

Indirect Victimization

In addition to the three microlevel theoretical ideas focused on neighborhood factors as key issues leading people to fear crime, there is a fourth one called 'indirect victimization.' There are multiple ways that one could be indirectly victimized, but research tends to focus on people learning about crime from friends, neighbors, community policing officers, television, and/or newspapers and therefore becoming afraid. Skogan (1986) argued that one of the key sources of information about crime is social networks – that is, talking to people we know (see also Tyler, 1980, 1984). Research on indirect victimization from other people is not as common as research on the impact of media sources, but those that have been conducted confirm that people can become more afraid or worried after talking to others about crime (see Lane, 2002; Covington and Taylor, 1991; Taylor and Hale, 1986). Research on the effects of community policing in particular sometimes shows that it

reduces fear of crime (e.g., Kelling et al., 1981; Roh and Oliver, 2005; Zhao et al., 2002), yet other research shows that it increases fear (e.g., Hinkle and Weisburd, 2008) or does not affect it (e.g., Scheider et al., 2003).

Researchers more commonly examine the impact of newspapers and television on fear of crime. Some research on newspaper effects finds that stories that are (1) more salient (e.g., near the front of the paper) or (2) more sensational or random and occurring locally increase fear (Heath, 1984; Liska and Baccaglini, 1990; Williams and Dickinson (1993)). However, other studies find that reading newspapers does not increase fear (Chiricos et al., 1997a; Perkins and Taylor, 1996) or that it decreases it for some people (e.g., Whites but not Latinos) (Lane and Meeker, 2003a). Research on the impact of television on fear typically finds that results depend on the audience characteristics and type of programming. In the 1970s, George Gerbner and his colleagues argued that people who watched a lot of television would be more afraid, regardless of their personal characteristics (Gerbner and Gross, 1976; Gerbner et al., 1977, 1978). This became known as the 'cultivation hypothesis,' and subsequent studies testing the idea found that once personal characteristics were taken into account, television viewing often did not impact fear (e.g., Hirsch, 1981; Hughes, 1980; Potter, 1986; Reith, 1999; Sacco, 1982; Tyler, 1984; Wober, 1978). Other studies, however, found that television mattered only for certain people or in certain areas (e.g., urban or high-crime areas) (e.g., Chiricos et al., 1997a, 2000a; Doob and Macdonald, 1979; Gerbner et al., 1980; O'Keefe and Reid-Nash, 1987; Schlesinger et al., 1991).

Current and Emerging Trends in Research and Theory

In summary, over time research has changed focus from personal characteristics alone to developing theoretical ideas about why personal characteristics might matter and to continually improving the validity, reliability, and specificity of fear-of-crime measures. There have been some recent trends that deserve additional mention. First, some research has focused on explaining how the individual theoretical models, while distinct, actually connect in some people's minds (e.g., Lane, 2002; Taylor and Hale, 1986; Lane and Meeker, 2003b, 2011). Second, in an effort to increase our understanding of fear and its impact on different people, research has focused on further refining samples, measures, and analysis approaches. One trend has been to examine fear in groups other than the general population of adults, including juvenile and adult offenders, who have more personal experience with crime (Lane, 2006, 2009; Lane and Fox, 2012, 2013; May, 2001a; May et al., 2002), and young people, who have less life experience (e.g., Brown and Benedict, 2004; De Groof, 2008; Irwin, 2004; May and Dunaway, 2000). Another trend has been to disaggregate samples to understand the differential impact of the theoretically important factors on different subsets of the population (e.g., women versus men, old versus young, minorities versus whites, and gang members versus nongang members) (e.g., Chiricos et al., 1997a, 1997b, 2000b; Cook and Fox, 2012; Ferraro, 1996; Lane and Fox, 2012, 2013; Lane, 2009; Lane and Meeker, 2003c, 2004, 2005, 2011; May 2001b). Moreover, recent research has pointed to the idea that although people often are more afraid than their victimization risk would warrant, the frequency and intensity of these fears are critical pieces of the puzzle that have not received enough attention. For example, Farrall and Gadd (2004) argued that people are not frequently afraid, having only a few episodes of fear per year. They also found that feelings of fear are not necessarily that intense when they occur.

In fact, Farrall et al. (2009) put forth the most recent theoretical ideas about fear of crime, beyond the incremental revisions of earlier ideas that have resulted from the wealth of studies on fear that have occurred over time. These scholars argued that fear of crime can be experienced in many ways, and they focus especially on the important differences between 'experiential' and 'expressive' fear. In their opinion, experiential fear occurs for those people who live in disordered and high-crime areas and face real objective risk of victimization, or real social vulnerability, as Skogan and Maxfield (1981) long ago discussed. That is, these people have experienced crime and know what it can do. They face real and powerful threats to their own safety and have episodes of intense emotional fear. According to Farrall et al. (2009), expressive fear of crime, in contrast, is much more common and is more about worries that people have about societal issues more generally and about their general feelings of insecurity. These issues of concern might include lack of social control, a lack of positive interactions with unknown people, and, as Merry (1981) first noted, a feeling that they cannot trust people who are different than they are to behave appropriately. These scholars argue that people have more general uneasiness rather than a lot of specific moments of intense emotion (Farrall et al., 2009), an idea that is reminiscent of Wilson's (1968) argument that people feel an "urban unease," which at its base is a concern about the failure of their communities and a lack of trust in others to follow accepted societal codes of conduct.

Summary and Conclusions

This article has focused on the study of fear of crime, which is more common than victimization. Fear is important because it has the potential to lead to behavioral precautions, which at one end of the spectrum can be passive but life altering (such as refusing to leave the home) or, at the other end, can be active and criminal (such as carrying weapons or joining a criminal street gang). This document first discussed the definition of fear (an emotional reaction) and then discussed how scholars have worked to better their measurements of the construct over time. Next came a discussion of the personal characteristics that are related to crime fear and the theoretical ideas that have been developed to explain the connections between demographic factors and fear. These ideas include vulnerability, neighborhood factors (subcultural diversity, disorder, and community concern), and indirect victimization. Finally, we discussed current and emerging trends in research and theory, including studying fear in different types of samples, disaggregating samples to examine the differential impacts of the theoretical factors on different groups, and pushing for research that

examines the frequency and intensity of fear emotions and realizes that fear can mean different types of reactions depending on the person.

Abstract

The mammalian startle response is a cranial-to-caudal spreading wave of flexor movements elicited by abruptly occurring sensory events. This protective reflex is reliably potentiated when elicited during fear states in both animals and humans a phenomenon that has been named the *fear-potentiated startle*. Systematic research in rodents has uncovered the neural circuitry that is involved in the fear-induced potentiation of the startle reflex. Numerous studies have pinpointed the amygdala as the key structure involving the basolateral amygdala (input region) and the central amygdala (output region) that projects via the periaqueductal gray to the brain stem modulating the neural transmission in the primary acoustic startle pathway. Measuring the eyeblink component of the acoustic startle reflex is has been demonstrated that the human startle reflex is reliably potentiated when elicited during cues that have been previously paired with aversive events. This fear-potentiated startle is impaired in patients with unilateral lesions of the amygdala and completely blocked with bilateral lesions of the amygdala. In an effort to translate these encouraging empirical findings obtained in parallel both from animals and humans to the clinic this neuroscience and emotion science-based approach and methodology has been used to investigate emotional reactivity, fear learning, and memory in patients across a broad spectrum of emotional disorders. Accumulating evidence across laboratories suggests that the defense system is overactive to threat cues in the early development of an anxiety disorder. Defensive response mobilization generalizes more easily and is particularly enhanced in contexts in which unpredictable and uncontrollable aversive events occur. With increasing comorbidity, chronicity, and severity of the disorder blunted defensive responses occur.

Potentiation of the Mammalian Startle Response during Fear

In its full expression the mammalian startle response is a cranial-to-caudal spreading wave of flexor movements along the neural axis that is elicited by an abruptly occurring sensory event of a certain intensity (e.g., a sudden noise, a sharp movement, or a sudden tactile stimulus; Landis and Hunt, 1939). The startle response has been observed in many species and appears to be a protective reflex to prevent injury. In humans, the startle response consists of the following set of muscle movements: closure of the eyelid, forward head movement, raising and drawing forward of the shoulders, abduction of the upper arms, bending the elbows, pronation of the lower arms, forward movement of the trunk, contraction of the abdomen, and bending of the knees (see Davis, 1984). One of the most striking features of the startle response is that it is reliably potentiated if the organism is in a state of fear.

In their pioneering fear-conditioning experiment with rodents, Brown et al. (1951) used a light-tone compound stimulus as the conditioned stimulus (CS) and a footshock as the unconditioned stimulus (US), reasoning that anticipation of impending painful stimulation results in a conditioned fear response (fear was considered to be a learned drive at that time, Miller, 1948). The startle eliciting stimulus in this experiment was the sound resulting from firing a toy pistol two feet from the confinement box with drilled holes on top of the box (Brown et al., 1951). The whole-body startle response to the explosive sound was measured by scoring the deflections of the platform at the bottom of the box. Startle probes presented during the CS that has previously been associated with the painful US-evoked larger startle responses of the rats than probes presented during the same stimulus in the control group where this stimulus was never paired with the US. A series of follow-up studies provided evidence that this phenomenon – which has been termed the "*fear-potentiated startle effect*" – is indeed caused by a central fear state and not by other factors. Davis and Astrachan (1978) found a robust potentiation of the startle reflex after fear conditioning, independent of whether the shock US was administered to back or to the foot of the animal. Thus, the alternative explanation that a special body posture (e.g., crouching; Kurtz and Siegel, 1966) might have caused the startle potentiation was ruled out. Moreover, drugs that have anxiolytic effects in humans (e.g., diazepam) reduce the fear-potentiated startle effect in animals (Davis, 1979). By contrast, substances that induce fear in nonanxious individuals and increase symptoms in anxiety disorder patients (e.g., yohimbine) lead to increase in startle potentiation (Davis et al., 1979; see Davis, 1986, for review).

Neural Networks of the Fear-Potentiated Startle

Our understanding of the brain's neural circuitry underlying the fear-induced potentiation of the startle response comes primarily from neuroscience research with rodents and has been extensively investigated by Davis and colleagues (for reviews see Davis, 1998, 2000; Davis and Whalen, 2001; Davis et al., 2010). This neural circuitry is sketched panel (a) of **Figure 1**.

The *primary acoustic startle pathway* in rodents consists of three synapses (Davis, 1998). When the acoustic probe stimulus reaches the ear the afferent neural volleys travel from the spiral ganglion cells in the cochlea to very large cells embedded in the cochlear nerve in rodents (and also in humans) named 'cochlear root neurons,' and then project via thick axon

Figure 1 (a) Photomicrographs prepared and provided by Dr Chungjun Shi of 30 μm horizontal sections through the rat brain, cut at a slight angle to include the amygdala and the bed nucleus of the stria terminalis (BNST) in the same sectional plane. The anterograde tracer biotinylated dextran-amine (BDA) was infused in the basolateral amygdala (BL). Strong connections exist to the central nucleus of the amygdala (Ce) and the BNST (reprinted from Davis et al., 2010. Neuropsychopharmacology Reviews, Nature Publishing Group). (b) Schematic diagram of the neural structures involved in the fear-potentiated startle reflex. Conditioned stimuli activate the basolateral amygdala. In the case of fear-potentiated startle outputs of the basolateral amygdala impinge on the primary startle circuit via projections from the central nucleus of the amygdala along the periaqueductal gray. The ventral part activates attentive freezing and startle potentiation while the dorsal part activates flight behavior.

collaterals directly to the nucleus reticularis pontis caudalis (RPC), the sensorimotor interface in the pons. Efferent projections pass from the RPC through the facial motor nucleus (blink reflex) or the spinal cord (whole body startle response) to the reflex effectors (Davis, 1998). The anatomical structures forming the primary acoustic startle pathway in animals are found in humans as well (Martin et al., 1990).

The phenomenon of startle potentiation during fear conditioning suggests the existence of an additional *modulatory circuit*. Converging evidence now suggests that the amygdala and its many efferent projections may represent one of the key structures within this modulatory circuit. The basolateral amygdala receives sensory information from the thalamus, the hippocampus and the cortex. Depending on its previous association with either appetitive or aversive events the baso-lateral amygdala activates or modulates synaptic transmission in target areas appropriate to the reinforcement signal (or motivational valence) with which the sensory information has been associated. In case of appetitive cues, the basolateral amygdala activates the striatum organizing approach behavior toward the pleasant cue (Davis and Whalen, 2001; Lang and Bradley, 2010; see **Figure 1**).

If the sensory event has been associated with aversive stimuli, such as pain or dyspnea (shortness of breath), this sensory event changes neural transmission in the basolateral amygdala which projects to the central amygdala. Pathways from the central amygdala project to a variety of hypothalamic, midbrain and brain stem target areas producing the somatic, autonomic and endocrine signs of fear, including the *fear-potentiated startle*. Indeed electrical stimulation of the central amygdala elicits fear like behaviors including startle potentiation. In contrast, lesions of the central amygdala block fear-potentiated startle to cues that have been associated with shock (Hitchcock and Davis, 1986, 1991). The central amygdala projects via the ventral amygdalofugal pathway to the nucleus RPC in the brainstem, modulating the neural transmission in the primary acoustic startle pathway. There is evidence from Koch (1999) suggesting that a synaptic connection between the amygdalofugal pathway and the periaqueductal gray (PAG) is required for the fear-potentiated startle. Recent evidence suggests that there are parallel downstream pathways from the central amygdala that activate distinct patterns of a fear response (Gross and Canteras, 2012). Efferents from the central amygdala to the ventrolateral part of the PAG are crucial for interrupting ongoing behavior, promoting attentive freezing, and potentiation of the startle reflex. In contrast, activation of the lateral and dorsolateral part of the PAG initiates a flight behavior associated with sympathoexcitatory responses like tachycardia, hypertension, and redistribution of the blood flow (Benaroch, 2012). Moreover, infusion of low doses of potassium cyanide (KCN) facilitates escape behavior elicited by electrical stimulation of the dorsolateral PAG, while lesions of the dorsolateral PAG abolish KCN-evoked escape behavior (Schimitel et al., 2012). These animal findings are complemented by recent human data from our laboratory showing that freezing is associated

with potentiation of the startle reflex while escape behavior is indeed associated with a relative inhibition of the startle response (Hamm et al., 2014).

The Role of the Bed Nucleus of the Stria Terminalis (BNST)

In 1997 Walker and Davis made the observation that in rats startle responses were not only potentiated when elicited during cues that have previously been associated with aversive US conditions but also when elicited during exposure to light compared to startle responses to the same acoustic probes administered in the dark. This phenomenon has been named "*light-enhanced-startle*" effect. Interestingly this light-enhanced startle was reduced by both benzodiazepine and non-benzodiazepine anxiolytics (Walker and Davis, 1997, 2002). Interestingly, while fear-potentiated startle to a short (3.7 s) light CS that has been paired with a painful footshock is blocked by lesions or the central amygdala or by pharmacological blockade of the alpha-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptors in this area, startle facilitation during long-lasting (20 min) exposure to bright light was unaffected by these manipulations. Lesions or local infusion of the AMPA antagonist NBQX into the BNST-blocked light-enhanced startle but left fear-potentiated startle to cues associated with aversive events intact. Since rodents are nocturnal and exhibit anxiety in open and illuminated spaces, one could argue that this environment creates a state of uncertainty about potential danger, typically described as anxious apprehension or worry. More recent animal data suggest that light-enhanced startle can be inhibited in a dose-dependent way by an oral administration of the corticotropin-releasing hormone (CRF) receptor 1 antagonist. Infusions of CRF into the lateral cerebral ventricle also markedly increased acoustic startle amplitudes in rats. Lesions of the lateral BNST completely blocked CRF-enhanced startle suggesting that this area is activated during states of anxious apprehension in uncertain contexts while the amygdala is more important for startle potentiation during short stimuli that were associated with aversive events (see for a review Davis et al., 2010). Interestingly, humans who are diurnal show the same facilitation of their startle response to probes presented during darkness (Grillon et al., 1997; Melzig et al., 2007), or during context conditions where unpleasant events occur in temporally unpredictable way (Grillon and Davis, 1997).

Fear-Potentiated Startle in Humans

To study the phenomenon of fear-potentiated startle in humans the movement of the eyelid, the most reliable and fastest component of the startle reflex sequence is recorded. Although many different procedures have been used to quantify the startle-eyeblink response (such as potentiometric, photoelectric, vertical electrooculographic, and magnetic search coil methods), most researchers currently record the electromyographic activity of the orbital portion of the orbicularis ocular muscle using miniature surface electrodes (see Lang et al., 1990; Blumenthal et al., 2005). Since the startle reflex can be elicited by any abruptly occurring sensory event of a certain intensity, electrical, mechanical (e.g., discrete taps or airpuffs to skin areas innervated by the trigeminal nerve), and visual (sudden increase in illumination) stimuli have been used in human research to elicit the startle reflex. However, the most commonly used startle-eliciting stimulus in human research is the acoustic probe stimulus, a 50-ms burst of white noise at an intensity of 95–100 dB presented with an instantaneous rise time.

Using this methodology the startle reflex has been used extensively to probe fear states of human beings. First in an effort to translate findings in rodents to humans it has been demonstrated that the startle eyeblink response is reliably potentiated in humans – like in rodents – when elicited during a cue that has previously been paired with an aversive electric shock. That is, during extinction startle responses are greater in magnitude (potentiated) to acoustic probes presented during previously fear-conditioned stimuli than during nonreinforced control stimuli or during the intertrial interval (ITI) (Hamm et al., 1993). Animal research suggests that startle potentiation might provide a direct metric for the assessment of defense system activation modulated by neural circuits including the amygdala. Thus, startle potentiation should be specific for fear learning and should not occur if behaviorally significant but nonaversive US conditions are associated with the conditioned stimuli. Following this reasoning Hamm and Vaitl (1996) completed a conditioning study with 100 participants in which for one group one (CS+) of two conditioned stimuli (pictures of neutral faces) was followed by an aversive electric shock during acquisition while the other neutral face (CS−) was never paired with the aversive US. To discriminate the acquisition of a fear response from pure cognitive learning of the contingencies another group saw the same two faces as conditioned stimuli, but in this case the CS+ was associated with a motivationally significant but nonaversive US (participants had to press a button when sensing a vibratory stimulus at their forearm and received a financial reward depending upon their reaction time), while the CS – was again never paired with this stimulus. The main findings of this experiment are depicted in the upper panel of **Figure 2**.

As in rodents, there was a clear potentiation of the startle reflex to probes that were presented during the reinforced stimulus (CS+) both compared to the nonreinforced CS – and to the probes that were presented in the absence of any visual foreground stimulus (ITI). Most importantly, the potentiation of the human startle reflex only occurred if the conditioned stimulus was associated with an aversive event and was absent if the CS was an imperative stimulus for a reaction time task. In contrast skin conductance responses – an index of orienting to significant (e.g., novel or arousing) stimuli (for review see Bradley, 2009) – were larger for the CS+ relative to CS – in both groups, i.e., independent whether the US was aversive or not. These data that have been replicated many times (Nitschke et al., 2002; Weike et al., 2007, 2008) clearly support the view that the startle potentiation is indeed a direct metric for the acquisition of a fear response.

Animal data show that bilateral lesions of the amygdala abolish fear-potentiated startle suggesting that the amygdala is

Figure 2 (a) Mean startle blink response magnitudes elicited during the presentation of the conditioned stimuli (CS+ and CS−) and the intertrial interval (ITI) and potentiation scores (CS+ minus CS−) during acquisition and extinction using an aversive shock (left panel) or a nonaversive reaction time task (right panel) as unconditioned stimulus in a differential delay conditioning experiment with healthy individuals. (b) Mean conditioned startle blink response potentiation for patients with unilateral temporal lobectomy and age matched controls, before, during, and after classical fear conditioning. (c) Potentiation (black bars: CS+ minus ITI; striped bars: CS− minus ITI) of startle response magnitudes as a function of genotype and stimulus. Results are shown for 5-HTTLLPR genotype groups (left) and for COMTval158met genotype groups (right) during conditioning (upper panel) and extinction (lower panel).

one key component of the neural circuitry modulating fear-potentiated startle. Following up on these animal findings Weike et al. (2005) completed a fear-conditioning experiment (identical to the one reported above) with 30 patients suffering from medically intractable unilateral temporal lobe epilepsy who had to undergo neurosurgery. For 18 patients the resections of the temporal lobe (amygdalahippocampectomy) involved the left anterior part of the temporal lobe (4.5 cm from the left temporal pole) in 12 patients the right anterior temporal lobe (5.5 cm from the right temporal pole). The bottom panel of Figure 2 (panel (b)) shows the main findings of this study.

Fear-conditioned startle potentiation was not completely abolished but significantly impaired in patients with unilateral lesions of the amygdala compared to healthy controls. These impairments were independent of lesion sites. Importantly, those patients who showed clear learned discrimination in skin conductance also exhibited clear impairment in fear-potentiated startle, suggesting that impairment of fear-potentiated startle was not due to a general learning deficit in these patients. Intact skin conductance conditioning for these patients was also reported by Coppens particularly when attention was explicitly allocated to the conditioning task by instructing the patients to provide shock expectancy ratings during each learning trial (Coppens et al., 2009). In contrast, and supporting the findings described above fear-potentiated startle was completely blocked in a group of four female subjects with Urbach–Wiethe disease from the Northern Cape of South Africa although half of these subjects learned the contingencies as assessed by verbal report data (Klumpers, 2012).

Recent behavioral genetic studies suggest that acquisition and also the extinction of fear-potentiated startle is modulated by genetic polymorphisms. Hariri et al. (2002) showed that a polymorphism in the promoter region of the human serotonin transporter (5-HTT) gene (*SLC6A4*) is related to amygdala activity evoked by threat cues, i.e., carriers of the short allele (a 43bp deletion) of the 5-HTT promoter (5-HTTLPR) show increased amygdala activation during viewing of fearful faces compared to long allele carriers. Based on these findings Lonsdorf et al. (2009) tested fear-potentiated startle in 5-HTTLPR s-allele carriers ($N = 30$) and l/l homozygotes ($N = 18$). In this study, on day 1 (Acquisition) one of two angry faces was associated with a highly annoying aversive unconditioned electrical stimulus while the other angry face was never paired with the US. After consolidation of the associative fear memory over night, extinction (both faces were presented without any US) started on the second day. Again startle probes were presented both during CS+, CS− and the ITI both during acquisition and extinction. The main findings of this study are depicted in panel (c) of Figure 2. As can be seen on left side of panel (c), only carriers of the 5-HTTLPR s allele acquired a significant

potentiation of the startle during cues that were associated with an aversive event through Pavlovian conditioning. In contrast long/long carriers did not show significant fear-potentiated startle. In this study, individuals were also screened for a second single nucleotide polymorphism on a gene coding for catechol-*O*-methyltransferase (COMT). Carriers of the met-allele have a fourfold reduction in enzyme activity compared with carriers of the val-allele, and as a result have higher extracellular dopamine levels particularly in the prefrontal cortex. Interestingly, acquisition of fear-potentiated startle was not affected by this genetic polymorphism. In contrast extinction of fear-potentiated startle was stronger for the val-allele carriers but was not affected by the 5-HTTLPR clearly supporting animal data showing that networks involved in fear learning differ from those involved in fear extinction (Quirk and Mueller, 2008). These genetic data are in line with findings from functional imaging studies showing that the acquisition of fear is associated with increased activation of the amygdala while extinction of the fear response requires activation of medial prefrontal cortical areas (Büchel and Dolan, 2000; Phelps et al., 2004; Milad et al., 2006). Klumpers et al. (2011) also found stronger fear-potentiated startle in individuals carrying at least one short allele for the 5-HTTLPR polymorphism compared to the long allele homozygotes, thus replicating and extending the findings of Lonsdorf et al. (2009). Moreover, using a context conditioning design in which aversive events occurred in one context at unpredictable times while no aversive stimuli were presented in another safe context, Glotzbach-Schoon et al. (2013) found stronger startle potentiation during the anxiety context in carriers of the short allele for the 5-HTTLPR who also carried the risk allele of the neuropeptide S receptor. Using also a context conditioning paradigm Heitland et al. (2013) again found increased potentiation of the startle reflex during aversive context conditions in short allele 5-HTTLPR carriers, who also carried the risk allele for the CRF receptor 1, a transmitter system which is particularly involved during startle enhancement in uncertain context conditions.

Using Fear-Potentiated Startle to Study Clinical Problems

In an effort to translate these basic findings from animal and human research to clinical problems, Hamm et al. (1997) first demonstrated that individuals with animal phobia showed a clear potentiation of the startle reflex when confronted with pictures of their feared animals (either snakes or spiders). Potentiation of the startle reflex evoked during viewing of these phobia-specific cues was significantly stronger than the facilitation of the startle reflex that was observed during viewing of other unpleasant but nonphobia-relevant pictures. These findings were replicated and extended by McTeague et al. (2012) who found a marked potentiation of the startle reflex in patients with specific phobia when probes were presented during imagery of personal narratives representing each patient's primary clinical fear. Again startle potentiation exceeded increase in startle magnitudes evoked during imagery of standard negative text (e.g., survival threat). Interestingly, this fear specific startle potentiation was more pronounced for patients who were diagnosed with a single specific phobia as principal diagnosis. Patients who were diagnosed with a different principal diagnosis (e.g., generalized anxiety disorder, adjustment disorder, etc.) but had a specific phobia as a comorbid diagnosis did show less startle potentiation during imagery of their personal fear scenes compared to patients with specific phobia as their principal diagnosis. Moreover, these patients with specific phobia as a comorbid disorder also showed more general negative affectivity and stronger general impairment. These data suggest that the assessment of startle potentiation during activation of fear-networks might serve as a meaningful phenotype to characterize different subgroups of patients within one diagnostic category possibly providing some neuroscience-based evidence for distinct psychopathological mechanisms.

Interestingly, a parallel pattern of results was observed for patients with social phobia (McTeague et al., 2009). Using the same script-driven imagery paradigm McTeague and coworkers found again increased startle potentiation during imagery of personal fear scenes in those patients who reported circumscribed focal social fears (like public speaking, performance fears, etc.), paralleling the findings for patients with circumscribed specific phobia. In contrast, those patients who had a more generalized social phobia, potentiation of the startle reflex was not specific for the personal fear but also generalized to other more standardized social situations. These data are in line with studies investigating fear-potentiated startle in patients with post-traumatic stress disorder (PTSD). Grillon and coworkers (Grillon and Morgan, 1999; Grillon, 2002) used a fear-conditioning paradigm to compare fear-potentiated startle in Gulf war veterans with and without PTSD. While PTSD patients did not differ from controls in the fear-potentiated startle during the cue that predicted the shock, startle responses elicited during the context in which the conditioning experiment took place was larger in the veterans with PTSD. Patients with PTSD had also larger startle magnitudes compared to patients with generalized anxiety disorder (GAD) when probes were presented during a context in which aversive events are unpredictable (Grillon et al., 2009). These data indicate that unpredictable and uncontrollable aversive events particularly activate defense response mobilization in these patients. Moreover, patients with PTSD also show impaired safety learning (Jovanovic et al., 2012). Inhibition of fear-potentiated startle by a safety cue presented in compound with the previously conditioned stimulus was reduced in PTSD patients. McTeague et al. (2010) found increased fear-potentiated startle in a large group of PTSD patients from a community sample with different trauma types during imagery of their personal traumatic narratives. In this PTSD-group a subgroup of patients was only exposed to a single trauma while another subgroup comprised patients exposed to two or more of such traumatic events (multiple-trauma subgroup). Enhanced startle potentiation was only observed in those PTSD patients with a single trauma. Multiple trauma patients showed no startle potentiation and a generally blunted physiological emotional response during imagery of their personal trauma. The multiple trauma patients had an earlier onset of their PTSD symptoms, reported more severe symptoms and showed greater comorbidity.

Following up on these findings, Limberg et al. (2011) investigated 40 nonmedicated patients with borderline personality disorder again using the script-driven imagery paradigm described above. Eighty percent of these patients had been exposed to traumatic events in the past and 26 patients in this group were also diagnosed with a comorbid current PTSD. Overall, startle modulation did not differ between borderline personality disorder patients and healthy controls, supporting previous findings (Herpertz et al., 1999), however, patients exhibited an increased potentiation of their startle responses during imagery of scenes describing rejection and abandonment, emotional schemas that are specifically relevant for these patients (Russel et al., 2007). Interestingly, blunted startle responses during imagery of personal trauma scenes was again observed in this study for those borderline patients with severe comorbid PTSD and the exposure to multiple traumas, probably reflecting a compromised defensive system after chronic exposure to severe stressors. Such explanation would be in line with animal data showing compromised defensive response mobilization in rats exposed to highly intense, prolonged, and inescapable shock.

Fear-potentiated startle has also been used to study psychopathology in panic disorder patients. Panic disorder patients report recurrent unexpected panic attacks (brief periods of intense fear accompanied by at least four out of 13 key symptoms including somatic symptoms) accompanied by at least 1 month of anxious apprehension about the implications or the consequences of the attacks or about having additional attacks in the near future. Importantly, for this group of anxiety patients the potential threat comes from inside the body. Therefore it might not come as a complete surprise that patients with panic disorder overall did not differ from controls in their potentiation of the startle reflex during anticipation of external nociceptive events (Grillon et al., 1994; Melzig et al., 2007). In contrast, if startle probes were presented during the perception of unexpected mild body symptoms, a clear potentiation of the startle response was observed for patients with panic disorder (Hamm et al., 2014) and in individuals who are at risk to develop a panic disorder (Melzig et al., 2011). In these studies, a voluntary hyperventilation procedure was employed where participants were guided to increase their respiratory rate and/or tidal volume exceeding the physiological demand, leading to a rapid drop in blood partial pressure of carbon dioxide, thus evoking typical body symptoms such as heart racing, dizziness, etc. Melzig et al. (2011) presented startle probes during early recovery from this hyperventilation procedure, because the pCO_2 level is still below 30 mmHg for approximately 2 min and body symptoms are still present without the interference of the task itself. As predicted, startle response magnitudes were substantially potentiated in individuals scoring high on the anxiety sensitivity index a risk factor for the development of a panic disorder. Accordingly patients with panic disorder and agoraphobia also showed increased potentiation of the startle reflex relative to age-matched controls when probes were presented during a 10-min recovery period after hyperventilation. Importantly, the amount of fear-potentiated startle during the perception of unexpected mild body symptoms was larger for those patients with a more severe symptom score on the panic and agoraphobia scale (Hamm et al., 2014). Panic disorder patients not only show increased defense response mobilization during perception of mild body symptoms they also show increased fear-potentiated startle during context conditions in which unpredictable and uncontrollable aversive events occur (Grillon et al., 2008). Moreover these patients also exhibit stronger generalization of their fear-potentiated startle to cues that resemble the original cue that was associated with an aversive event (Lissek et al., 2010). These data suggest that these patients show enhanced anxious apprehension toward unpredictable and uncontrollable events (like panic attacks) and that this defensive mobilization generalizes very easily to different situations thus providing a possible mechanism for the generalized avoidance behavior that is typically seen in patients with panic disorder and agoraphobia.

This translation of the fear-potentiated startle paradigm into the clinical research domain has provided very promising results leading to a better understanding of psychopathology from a neuroscience perspective. Moreover, fear-potentiated startle has also been used recently to elucidate the mechanisms involved in eliminating fear reactions to aversive events. Kindt et al. (2009) demonstrated that the oral administration of the beta-adrenergic antagonist just prior to the reactivation of the fear-conditioned memory abolished expression of fear-potentiated startle 1 day later, thus preventing reconsolidation of fear memories. Following up on these findings Sevenster et al. (2013) demonstrated that this disruption of reconsolidation and blockade of fear-potentiated startle requires active new learning, i.e., inducing a prediction error, the experience that an expected aversive event is no longer associated with the cue. The consolidation and reconsolidation of fear memories as indexed by fear-potentiated startle is modulated not only by the monoaminergic system but also by the glutamatergic system. In a series of experiments it was demonstrated that extinction of fear-potentiated startle was facilitated by administering the *N*-methyl-D-asparate (NMDA) receptor (glutamate acts on the NMDA receptor) partial agonist D-cycloserine either systemically or directly into the basolateral amygdala (Walker et al., 2002). Clinical studies that systematically test the effects of such pharmacological support of exposure therapies are under way (Davis et al., 2005; Hofmann et al., 2006; Otto et al., 2010).

Abstract

Fear is an innate, behavioral–motivational system that allows humans and animals to rapidly enact specific defensive behaviors in response to stimuli that the system, either through natural selection or learning, has come to recognize as potentially dangerous. The fear system likely evolved due to the reproductive success it conferred animals that could most aptly avoid or escape encounters with predatory or environmental threats. While fear to certain kinds of stimuli is unlearned and seemingly biologically prepared, fear can also be acquired rapidly and lastingly to stimuli associated with harmful outcomes, allowing animals to respond adaptively to new environmental threats. This article will present some of the behavioral and physiological aspects of fear that make it a useful model system for understanding the psychological and neurobiological mechanisms of emotion, learning, and memory, as well as the development of a variety of human fear-related disorders.

Fear – Definition and Background

All organisms are subject to threats and dangers from their environments, such as predation, dominance, and territoriality. Through the process of natural selection, evolution has endowed all organisms with defensive mechanisms (e.g., chemical toxins in plants; fight–flight responses in animals) for self-preservation. Fear serves this same purpose. In humans and other higher-order animals, 'fear' as a scientific term describes a behavioral–cognitive–emotional state in which a set of adaptive responses is activated in the presence of perceived danger. As the term is more commonly used, 'fear' refers to a sensation (or feeling) of strong unpleasant emotion aroused by stimuli or events that are perceived as threatening or dangerous.

This more anthropomorphic (psychological) sense of the word 'fear' may be useful in describing a person who is experiencing an environmental threat (e.g., snakes or extreme heights) and exhibiting certain stereotyped behaviors such as a fearful facial expression, autonomic arousal, behavioral readiness, and other defensive responses. However, it is probably inaccurate to use the term to describe the response of a goldfish (or any other lower-order animal) that is exhibiting similarly stereotyped behaviors (e.g., avoidance or escape) in response to painful physical stimuli such as electric shocks. In this article, fear will be defined as the coordinated pattern of brain activities, bodily changes, and adaptive behaviors that occurs within an animal in response to perceived threats and dangers.

A repertoire of innate fear responses that is characteristic of a particular animal species is often referred to as species-specific defensive reactions (SSDRs; Bolles, 1970) (**Figure 1(a)**). For instance, the universal expressions of fear in humans include particular facial expressions (seen in members of all cultures), changes in autonomic nervous system activities (e.g., increased heart rate, increased blood pressure, rapid respiration, perspiration, elevated pain threshold, pupil enlargement, and decreased digestive activity) and behavioral readiness (e.g., freezing, increased propensity to startle, and sharpening of cognition) (see LeDoux, 1996). These fear responses in humans are 'hardwired' (innate) as indicated by the observation that newborn infants, when exposed to aversive stimuli (e.g., a loud noise) for the very first time, exhibit responses such as sudden eye closure, rapid breathing, clutching of the hands, and crying (e.g., Watson and Rayner, 1920). The innateness of the fear response is also demonstrated in other animals; for example, laboratory-reared rats confronted with a live predator (e.g., a cat) or its odor for the very first time exhibit changes in the autonomic nervous system and behavioral readiness (responses that are remarkably similar to those seen in humans), and emit ultrasonic (22 kHz) distress vocalizations (a response that is an example of an SSDR) (Bolles, 1970). The advantage to survival, and therefore reproduction, conferred by such automatic responses is a logical consequence, but only recently have researchers begun to study the ecology of fear.

The ability to learn about potential threats or dangers is another important adaptive aspect of the fear system. For instance, although newborn infants innately exhibit fear to certain stimuli, they do not show innate fear to flame or height (two stimuli that most children learn and adults remember to avoid). A stimulus that initially does not evoke a fear or defensive response can develop that ability after the organism experiences the pain and/or physical stress associated with encountering that stimulus. This allows an organism to develop a rapid, automatic response to new threats in the environment. Fear learning, as opposed to reward learning (*see* Reinforcement: Neurochemical Substrates), can develop within as few as a single experience with the stimulus and its consequences. It can also be quite lasting, potentially for an entire lifetime, as is often seen with untreated cases of fear-related disorders (discussed later). Indeed, this calls into question the extent to which the fear system can generate adaptive behaviors, as fear-related disorders are often extremely debilitating to the individual.

Fear as an emotion has been a topic of interest to many subdisciplines of psychology, including psychoanalysis, behaviorism, cognitive psychology, and biological psychology. Historically, two opposing theories of emotion, the James–Lange theory and the Cannon–Bard theory, have been especially influential (**Figure 2**).

According to the James–Lange theory, threatening or dangerous stimuli trigger physiological arousal and behavioral responses (via the autonomic nervous system), which are

Figure 1 Simple models of innate fear and fear conditioning. (a) Innate fear: perceived danger triggers a coordinated set of programmed behavioral and physiological responses, which prepares the animal to contend with the potential threat. (b) Fear conditioning: fear of novel stimuli can be acquired through the process of classical conditioning. By virtue of association with the fear-eliciting US and its UR, the CS comes to activate a fear CR. *The putative locus of neural plasticity involved in fear conditioning.

Figure 2 The James–Lange and Cannon–Bard theories propose different accounts by which threats and danger trigger fear emotions. The James–Lange Theory posits that fearful emotion is triggered when the brain detects the body responding reflexively to threatening or dangerous stimuli. In contrast, the Cannon–Bard Theory emphasizes the independence of fearful emotion from physiological arousal.

perceived and then processed as the experience of fear by the brain (emphasizing the importance of physiological feedback to the brain). In contrast, the Cannon–Bard theory posits that threats and dangers simultaneously trigger brain activities representing fear as well as initiate physiological arousal and behavioral readiness (emphasizing the importance of brain activity). Thus, the critical distinction between the two theories is whether the appearance of immediate danger (e.g., a bear) is postulated to activate the central fear system in parallel with fleeing and autonomic responses (Cannon–Bard theory), or to first trigger fleeing and autonomic responses, which are then detected and interpreted as fear by the brain (James–Lange theory). There is evidence in support of both theories, suggesting that central processes and bodily feedback both contribute to the emergence of fear as an emotion.

Because humans share many biological and behavioral features with other animals, experimental studies with nonhuman animals provide valuable information toward understanding the physiological as well as the psychological aspects of fear. Charles Darwin postulated in *The Expression of Emotions in Man and Animals* (1872) that emotions such as fear are innate, highly specific to situations, and the product of coordinated brain activities, and that different animal species with diverse environmental demands (or histories) have evolved dissimilar specialized sets of fear (or defensive) responses to maximize survival. It follows from this line of reasoning that more related species on the phylogenetic tree will exhibit more similar fear responses than will less related species, whose nervous systems share fewer characteristics. Indeed, studies have found similar patterns between humans and rodents in defensive responses to threatening stimuli and situations. Thus, it is highly likely that the neuronal substrates underlying fear (or other defensive mechanisms) in humans are more similar to those of other mammals (e.g., chimpanzees and rats) than those of nonmammalian animals (e.g., fish and birds).

Neuronal Substrates of Fear

The modern neurobiological study of emotion began in 1937 when James Papez published his description of a neuronal theory of emotion, connecting specific brain circuitry to emotional phenomenon, which came to be known as the Papez circuit. Intricate dissections of a human brain have found that this circuit begins in the hippocampus and runs through the fornix to

the mammillary bodies, to the anterior nucleus of the thalamus through the mammillothalamic tract, through the cingulum and to the entorhinal cortex, which connects back to the hippocampus to complete the circuit. In 1949, Paul D. MacLean expanded the Papez circuit in his conception of the limbic system (*see* Limbic System), a primitive but conserved autonomic emotional system, to include structures such as the amygdala, cingulate cortex, and areas of the prefrontal cortex. However, attempts to classify a specific, discrete circuit subserving emotional processes have proven to be difficult, though the efforts have generated a vast amount of information regarding the specific properties of emotion, particularly fear responses. Several lines of evidence point to temporal lobe structures (specifically the amygdala, an almond-shaped group of nuclei buried deep within the temporal lobes) as the key neural system underlying the central state of fear (see LeDoux, 1996). The classic studies of Klüver and Bucy (1937), who examined the effect of temporal lobe ablations in rhesus monkeys, were pioneering in this respect. Klüver and Bucy noted dramatic postlesion behavioral changes, including hyperactivity, hypersexuality, and a so-called 'psychic blindness' that was manifested as an apparent indifference to previously frightening and/or arousing stimuli. While the monkeys were wild and aggressive prior to surgery, they were remarkably tame and agreeable to human contact afterward, suggesting that a crucial emotive brain center had been removed or significantly affected by the lesions. Subsequent work, such as that of MacLean and Delgado (1953) using focal stimulation of temporal lobe structures in awake, behaving monkeys, pointed to the amygdala as the critical site. The importance of the amygdala in both innate fear responses and fear learning has been reconfirmed in numerous studies employing diverse species of animals (e.g., rats, mice, cats, rabbits, monkeys, humans) and various experimental techniques (e.g., lesions, stimulation, drug infusions, recordings), and most current theories of amygdalar function reflect the central role of the structure in the processing of fearful stimuli and enacting defensive behaviors. Consistent with this view, human neuropsychological and brain-imaging studies have found that patients with amygdalar damage are selectively impaired in the recognition of facial expressions of fear, and that there is a significantly increased amount of blood flow to the amygdala (as measured by functional magnetic resonance imaging) when normal subjects are presented with pictures of fearful faces (Adolphs, 2010).

The amygdala, as one of the principal structures of the limbic system, has access to sensory input from diverse areas of the brain (e.g., olfactory cortex, hippocampus, thalamus, hypothalamus, neocortex), and projects to various autonomic and somatomotor structures that mediate specific fear responses (e.g., bed nucleus of stria terminalis for activating stress hormones, periaqueductal gray matter for defensive behavior, lateral hypothalamus for sympathetic activation). Several subnuclei within the amygdala have been identified as having distinct functions, but the functions have yet to be fully characterized. The lateral amygdala (LA) receives input from the thalamus about sensory stimuli, and projects to the central nucleus (CeA) of the amygdala. Other subregions of the amygdala include the medial (MeA), basal (BA), and intercalated (ITC) nuclei. Different nuclei appear to be involved depending on the sensory modality of the fear-eliciting stimulus, and they each project to different structures throughout the brain, such as the hypothalamus and periaqueductal gray.

Given this pattern of connectivity, it is not surprising that damage to the amygdala eliminates stereotypical fear responses, such as defensive freezing (characterized as a motionless, crouching posture that functions to reduce the probability of detection by predators) exhibited by rodents in the presence of predators or perceived threats (Lavond et al., 1993). Nevertheless, while the amygdala is apparently an important component of the central fear-processing system, it does not necessarily follow that the amygdala is the seat of fear as an emotion (or a feeling). Given its intricate reciprocal connections with the neocortex, a structure implicated in higher cognitive functioning, it is very likely that the interactions between amygdala and neocortex (particularly sensory and limbic association cortices) are responsible for the emotion of fear. Thus, although the amygdala is essential in activating various fear responses (or SSDRs) both in humans and in rats, the fact that there are great differences in the neocortices of humans and rats suggest that perhaps there might be important differences in fear as experienced by the two species. Nonetheless, novel methods of physiological measurement and ways to analyze behavior are constantly being generated to solve the unanswered questions about fear and the brain.

Contemporary Fear Research

Classical or Pavlovian fear conditioning has been widely employed for studying the mechanism(s) by which fear is acquired and processed in the brain. Fear conditioning occurs when initially neutral 'conditional' stimuli (CSs), such as tones, lights, or distinctive environmental settings, are contingently paired with aversive, 'unconditional' stimuli (USs) such as electric shocks or loud noises, which reflexively activate unconditional fear responses (URs). Through CS–US association formation, the CS comes to elicit various conditional fear responses (CRs) that are similar to innate fear responses (**Figure 1(b)**). Perhaps the best known example of fear conditioning is the Little Albert experiment by Watson and Rayner (1920). Little Albert was an 11-month-old infant who initially exhibited curiosity (no fear) to a white rat by touching and playing with it. Watson and Rayner attempted to condition Albert to fear the rat by striking a steel bar with a hammer behind his head (US) as his hand touched the rat, causing him to startle, fall forward, and cry (UR). A week later, when the rat (CS) was placed near Little Albert's hand, he withdrew his hand and began to cry (CR). This fear of the rat was also alleged to be observed in the presence of other white furry animals and objects (e.g., rabbits, dogs, fur muffs), indicating that acquired fearful associations can generalize to other similar stimuli.

Modern investigations of fear conditioning typically employ rats as subjects and use a tone as a CS and a mild footshock as a US. Under these circumstances, a single CS–US pairing results in robust (rapid and enduring) fear learning, as evidenced by a variety of conditional fear responses exhibited upon subsequent presentations of the tone. Thus, the biological significance of fear conditioning is reflected by the quick and nearly permanent nature of changes in the behavior toward

the initially neutral stimulus that has been paired with an aversive experience.

Fear can also be rapidly acquired through instrumental or operant conditioning, in which the presentation of an aversive stimulus is contingent upon the behavior of the animal. A widely employed procedure with rodents is the passive (or inhibitory) avoidance task. In this paradigm, the animal's response (e.g., entering a dark compartment of a box when placed in an adjacent lighted compartment, or stepping down from a platform onto a grid floor) is paired with an aversive experience (e.g., a footshock). As a function of this response–stimulus pairing, the animal learns to avoid making the response that was followed by the aversive experience.

While the benefits to survival conferred by fear learning are obvious, the mechanisms underlying the associations between CS and UR have been evolutionarily constrained in the kinds of associations that can be formed. For example, Garcia and Koelling (1966) demonstrated that while rats can associate a light/sound with a footshock as well as tastes with illness, they cannot learn associations between tastes and footshocks or lights/sounds with illness. The mechanisms underlying different kinds of fear learning have evolved as a consequence of common, natural associations encountered by ancestral organisms and do not have the facility to form associations between just any CS–US pairing. This principle of 'selective association' is important to consider when trying to understand the neuronal substrates of fear learning, as it suggests there are different neuronal circuits underlying the learning of different kinds of defensive responses.

Similar to innate fear, evidence from lesion, pharmacological, recording, and stimulation studies indicates that the amygdala is essential not only to innate fear, but also to the acquisition of fear, as with fear conditioning (see Lavond et al., 1993; LeDoux, 1996). Thus, amygdalar lesions (particularly lesions of the CeA) impair the acquisition and retention of various fear-related behaviors in rats, rabbits, and cats. Neurons in the amygdala are responsive to both CSs and USs and undergo plastic changes during fear conditioning. Furthermore, restricted stimulation of the amygdala elicits specific fear responses (e.g., freezing). A novel and increasingly popular method is 'optogenetics,' which has allowed a high degree of neuronal specificity for studying the substrate of fear. This technique employs viral gene insertions to manipulate genetic transcription within neurons so that they generate receptors that are uniquely sensitive to light stimuli, thus permitting researchers to activate very specific neuronal circuits or subpopulations with implanted optical fibers (see Deisseroth, 2011). In a recent study, Johansen et al. (2010) used optogenetic stimulation in rats to demonstrate that activation of neurons within the LA drives the association between an innocuous stimulus and a fear response during fear learning.

Recent findings from human studies also indicate that the amygdala is critically involved in fear learning and fear responses. Ralph Adolphs and colleagues identified a patient (SM) as having rare, bilateral amygdalar lesions who exhibited a remarkable lack of overt and subjective fear responses to common fear-eliciting stimuli such as live snakes and spiders. Furthermore, many studies show that blood flow to the amygdala is increased during fear conditioning in normal subjects, further adding to the evidence that the amygdala is crucially involved in fear learning (see Adolphs, 2010).

One hypothesis of amygdalar function in fear conditioning is presented schematically in **Figure 3**. In this model, an emotional stimulus (such as a tone that has been paired with a footshock) is presented, and its sensory characteristics are processed by way of two parallel pathways that ultimately converge in the amygdala. One of these pathways is 'direct,' and provides relatively 'raw,' unprocessed information about the stimulus very quickly. This pathway projects through the thalamus to the amygdala. The second pathway is 'indirect,' and provides highly processed information about the stimulus but does so at the cost of an increased processing time (LeDoux, 1996). If the neocortex is the seat of conscious awareness, the thalamic pathway to the amygdala can be considered the subconscious (nondeclarative or implicit) fear route while the cortical pathway can be considered the conscious (declarative or explicit) fear route. This cortical pathway consists of projections through the primary sensory cortices to higher-order association areas as well as the hippocampal formation, which then projects to the amygdala. Upon reaching the amygdala (specifically the lateral/basolateral nuclei), the two converging representations of the stimulus are subject to additional processing within the amygdala itself. Most current theories assume that the essential plasticity underlying this form of learning occurs in the amygdala and corresponds to a neural instantiation of the association between the CS (the tone) and the US (the footshock) long assumed by psychologists to lie at the heart of classically conditioned behavior. This plasticity is widely believed to be mediated by the synthesis of new proteins within amygdalar neurons (*see* Synaptic Mechanisms and Protein Synthesis in Learning, Memory). The regions involved in forming and maintaining CS–US

Figure 3 A simplified putative fear-conditioning circuit. Conditional stimuli (e.g., tone or light) are processed via two separate pathways to the amygdala, where associations between the US and CS are thought to form. One pathway is via the direct (1) thalamoamygdalar projections (subcortical) and the second is via the indirect (2) corticoamygdalar projections (cortical).

associations are still unclear, though new clues are being discovered by researchers investigating how humans and animals update memories of fearful associations in a process called 'reconsolidation.'

Reconsolidation, though a controversial topic among researchers, is theorized to occur when a previously acquired long-term memory trace is reactivated (or retrieved), becomes labile, and is therefore subjected to new modifications, likely through changes in neuron-specific protein transcription. The nature of the modification may be to strengthen the memory, to change the properties of the stimulus associated with a given aversive outcome, or to weaken the association (as in 'unlearning'). This hypothesized process of unlearning, which is essentially an erasure of the original memory, might be possible through blocking reconsolidation of a memory after it has become labile (see Section Fear Pathologies and Clinical Implications). Unlearning is distinct from inhibition of the original memory (i.e., the conditional response to a CS), which requires new learning and the original memory remains intact. This process of learned inhibition is called 'extinction' and occurs when the CS no longer predicts the US (Pavlov, 1927). This is readily modeled in fear-conditioning experiments when a US stops occurring with a CS, and, over many trials, the animal reduces the magnitude and frequency of its fear responses to the CS. The animal learns that it no longer needs to be afraid of the CS, and the conditional response is 'extinguished.' Extinction learning permits an animal to readapt to environments where particular threats or dangers are no longer present, providing new opportunities for foraging and mating. There are limitations of extinction learning, as it is highly context specific and readily overridden by renewal of the original fear response.

Extinction learning is largely attributed to the workings of the prefrontal cortex, a relatively new structure in the evolution of the mammalian brain, which has many intricate, reciprocal connections with the amygdala. Two areas in particular have been implicated in regulating the amygdala: the infralimbic cortex and the prelimbic cortex. Stimulation and inactivation studies have begun to characterize these two areas as having opposing influences on the amygdala (Quirk et al., 2010). The infralimbic cortex carries inhibitory projections to the amygdala, apparently driving extinction learning, but the prelimbic cortex has an excitatory effect on the amygdala, increasing fear responses. The precise functions of the inputs to and outputs from the amygdala, as well as the intraamygdaloid processing of CS- and US-related information, remain a topic of intensive research.

Fear Pathologies and Clinical Implications

Fear conditioning and extinction serve as a model system for understanding not only the neural basis of acquired fear in nonhuman animals, but also the etiology of a variety of fear-related disorders in humans (e.g., anxiety, phobias, post-traumatic stress disorder (PTSD), and panic disorder). Since the characteristic behavioral and physiological symptoms of human anxiety disorders closely resemble many of the fear responses observed in fear-conditioning paradigms, it is possible that anxiety and fear are closely related (**Table 1**) (*see* Anxiety and Fear Conditioning, Neural Basis of). It is important to note, however, that the fact that the symptomatic manifestation of anxiety disorders is similar to the fear responses observed in fear conditioning does not necessarily mean that the underlying neuronal substrates of fear and anxiety are the same (post hoc, ergo propter hoc). While anxiety disorders can arise unpredictably, it is known that most patients experience their first symptoms in early adult life, indicating that maladaptive anxiety may be at least partly acquired. Indeed, clinicians from the time of Freud have speculated that anxiety patients have acquired their disorder as a result of traumatic learning experiences. Since the paradigm *par excellence* of traumatic learning is fear conditioning, fear conditioning appears to be useful in understanding the genesis of anxiety disorders (**Figure 3**).

The question of whether anxiety is analogous to fear conditioning might be one of semantics; the difference is between normal, adaptive fear and abnormal, maladaptive fear (anxiety, phobias). However, there is an important distinction between anxiety disorders and fear conditioning (e.g., Seligman, 1971) that might be taken to suggest that the two have very different bases. That is, while conditioned fear responses may be extinguished by, for example, actively preventing an animal from making escape or avoidance responses to a danger-signaling stimulus, fear-related disorders in humans (e.g., phobias) are quite resistant to extinction. In fact, anxiety disorders are characterized by fears that the patients recognize to be irrational but are unable to control.

Based on **Figure 3**, it is interesting to speculate that fear-related disorders (irrational fears) might be due to unbalanced activities in the cortical and thalamic pathways to the amygdala. For example, in most people a snake seen behind a glass window will elicit a different response than will a snake encountered in the woods. Both cortical and subcortical routes will process information about the snake, but the cortical (conscious) route will integrate the contextual information of the glass window and assess the safety of the situation (possibly

Table 1 Behavioral and physiological responses associated with anxiety disorders and fear conditioning

Anxiety disorders	*Fear conditioning*
Palpitations, accelerated heart rate	Increased blood pressure, tachycardia
Sensations of shortness of breath or suffocating	Increase in respiration, shallow breathing
Sweating	Increase in electrical conductance of skin
Nausea or abdominal distress	Suppressed appetite
Paresthesia (numbing or tingling sensations)	Hypoalgesia or analgesia
Hyperreactivity	Potentiated startle responses

acting as a gate). However, if the cortical pathway is somehow disrupted, the subcortical activity will be left unchecked to activate fear responses, even in an inappropriate context. It is possible that this type of unregulated subconscious activation of fear contributes to the etiology of fear-related disorders.

Figure 4 illustrates a hypothetical model of normal, adaptive fear and abnormal maladaptive fear. It is conceivable that genetic predisposition and environmental factors (e.g., stress) interact in such a way as to disrupt the normal balance between cortically activated fear and subcortically activated fear, leading to fear-related disorders. If it is then supposed, as some have suggested (LeDoux, 1996) that extinction is achieved through cortical inputs to the amygdala, and direct thalamic inputs are relatively resistant to extinction, it follows that fear disorders based on overactivity in the subcortical pathway should be 'irrational' in the sense that they do not subside even when the patient recognizes them as such. A more comprehensive understanding of the neuronal substrates and, subsequently, the molecular mechanisms of the fear system will be useful in understanding and developing treatments for fear-related disorders.

Several clinical populations have provided valuable information for understanding the contribution of different brain regions to fear-related disorders. Patients with Urbach–Wiethe disease, a rare, recessive genetic condition characterized in part by bilateral calcifications of the interior medial temporal lobes (particularly of the amygdalae), are cognitively comparable to normal patients, though they typically exhibit deficits in emotional processing (Adolphs, 2010). Patients with phobias exhibit a persistent fear to a specific object or situation (e.g., spiders, snakes, water, heights) and actively avoid encountering such object or situation, though often even the patients recognize their fears to be irrational, exaggerated responses. Phobias can develop as a result of traumatic experiences (e.g., being bitten by a snake, falling from a high place), or, as seen with innate fear responses, be biologically hardwired, though it is uncertain for what fears humans may be predisposed (see Seligman, 1971). Patients diagnosed with PTSD exemplify the interactions between stress, anxiety, and fear quite distinctly. PTSD develops as a consequence of direct or indirect (witnessing) traumatic experiences such as natural disasters, physical or sexual assault, or war; aspects of which (e.g., smells, sounds, and/or locations) become fear- and anxiety-inducing stimuli that are particularly resistant to extinction. Though resembling phobias in their persistence, such stimuli need only be reminiscent of the original trauma to elicit strong fears and anxiety in those suffering from PTSD. Treatment for patients suffering from fear-related disorders may be achieved through cognitive–behavioral and pharmacological interventions. Drawing heavily from the extinction literature, exposure therapy involves exposing the patient to their object or situation of fear in controlled, nonthreatening environments in order to dissociate the stimulus from the fear of danger. Extensive exposure therapy over the patient's lifetime is often needed to maintain an extinguished fear since the fears can be spontaneously reinstated. Other therapies often utilize structured social support groups and routine-based behavioral changes to help patients control their fear and anxiety. Pharmacological therapies have also drawn on extinction literature, using drugs that enhance inhibitory learning in order to extinguish fear responses. The majority of pharmacological treatments involves anxiolytic (anxiety-reducing) drugs, and may work best for managing the symptoms of a disorder in combination with cognitive–behavioral therapies. More recent pharmacological approaches have attempted to either block fear memories from forming (during initial consolidation) or erase fear memories after they form by blocking reconsolidation. Immediate application of beta blockers (e.g., propranolol) after a traumatic experience may prevent abnormal fear memories of the trauma from developing, though their success seems extremely time sensitive. Intensive research is currently being conducted to identify pharmacological and behavioral therapies that may block or disrupt reconsolidation and erase previously acquired fear memories.

Figure 4 A simple model of normal and abnormal fear based on the putative circuitry of cortical and subcortical fear-conditioning pathways. The subcortical fear route provides a quick but imprecise representation of sensory information for activating fear (a nonconscious pathway), whereas the cortical fear route provides relatively slower but more detailed information for activating fear (a conscious pathway). In normal fear expression, there is a balance between the cortical fear and subcortical fear pathways, such that the cortical component is stronger than or equal to the subcortical component. Abnormal fear might arise when this balance is disrupted such that the activity of the subcortical fear system overwhelms the activity of the cortical fear system.

Conclusion

The study of fear is but one means of understanding emotion, but it is the most fruitful one to have been employed to date. This is likely due to the primacy of fear: unlike other emotions, fear is apparently shared by a wide variety of species. This ubiquity speaks to its importance as a mechanism for self-preservation. Thus, fear has been the intense focus of researchers over the past century, and much has been learned about the biological substrate underlying innate and learned fear. However, precise understanding of how the various brain

regions known to be involved interact with each other to collectively function as a system – identifying potentially threatening stimuli, determining the appropriate response, and enacting that response – remains a topic of lively debate. Furthermore, little is known about the ways in which fear influences the daily behavior of many animals, including humans, though clinical populations clearly demonstrate such effects. Indeed, it seems that therapies for fear-related disorders have room for improvement yet, promising a future of continued research from diverse areas of study.

This article is a revision of the previous edition article by A. Burris, volume 8, pp. 5440–5442, © 2001, Elsevier Ltd., with revisons made by the Editor.

Abstract

Federalism refers to a set of institutional arrangements dividing power between a central government and regional governments. The term also refers to a philosophy of government that advocates federal arrangements as a desirable system of government. The relationship between federalism and related terms such as unitary government, federal system, and intergovernmental relations is clarified. The normative and empirical branches of the study of federalism are distinguished. Major arguments for and against federal systems of government are reviewed. Empirical studies of federalism are divided into those focusing on description and those focusing on causality. Within the descriptive realm, the core features of federal systems are delineated, and major federal systems of government are listed. Scholarly efforts to characterize variation within federal systems are described. The causes of the formation and dissolution of federal systems are discussed, along with efforts to understand the causes and consequences of change within federal systems. Areas likely to be of particular emphasis in future research are indicated.

'Federalism' refers to both an arrangement of political institutions and a philosophy of government. Federalism as a set of institutional arrangements denotes a political system in which power is shared between a central government and regional governments. Federalism as a philosophy of government holds that such federal structures are a desirable governmental form.

Federalism and Related Terms

The distinction between 'federalism' and related terms should be clarified. A government displaying the institutional characteristics of federalism is referred to as a 'federal system,' and the institutional structures themselves are described with the adjective 'federal.' A federal system is contrasted with a 'unitary system' of government in which all major decisions are made by the central government; some degree of administrative decentralization, however, may be present in a unitary system. The terms 'federalism' and 'federal system' have been used as overarching terms which encompass a variety of more specific types of political arrangements, including federations, confederacies, and leagues (Riker, 1975). The origins of the word 'federal' can be traced to the Latin *foedus*, denoting a league, treaty, or covenant. The term 'intergovernmental relations' refers to interactions between different governmental units within a political system. This term includes but is not limited to the study of interactions between central and regional governments within federal systems.

The Normative Study of Federalism

The study of federalism can be usefully divided into normative and empirical branches. The normative branch, which dates back centuries and remains very important today, includes the arguments in favor of the US constitution put forth in *The Federalist*. This normative literature consists of systematic consideration of federalism as a philosophy of government, including the enumeration of possible advantages and disadvantages of federal systems.

Proponents of federalism argue that federal systems are desirable because they may produce a number of advantageous consequences. In particular, advocates of federalism suggest that federal systems protect citizens against tyranny by dividing power among central and regional governments; expand possibilities for political participation by increasing the number of governments within a political system; allow for regional variations in public policy that are reflective of geographic differences in citizen preferences; and provide multiple governmental 'laboratories' in which innovative policy responses to public problems can be tested (Shapiro, 1995).

Other scholars have argued that federal systems may produce a variety of negative consequences. For example, federal systems may encourage regional inequalities in the distribution of the costs and benefits of public policies; allow for the oppression of local minorities by local majorities within the subnational jurisdictions; and produce an undesirable 'race to the bottom,' in which regional governments attempt to attract economic enterprises by lowering regulatory standards and reducing governmental taxation and expenditure (Shapiro, 1995).

The Empirical Study of Federalism

The empirical branch of the study of federalism has focused on the description and measurement of federal systems, and also on the establishment of relevant causal relationships.

Descriptive Approaches

In the descriptive realm, scholars have been concerned above all with identifying the core characteristics of federalism, characterizing variation in federal systems, and describing the mechanisms through which federal systems operate. At the

heart of the federal idea is the division of powers and responsibilities between an overarching central government exercising authority over a broad territory, on the one hand, and a number of constituent governments each exercising authority over a particular subset of that territory, on the other. This division of power is generally enshrined in a constitution that guarantees the existence of all of the governments and provides at least a rough outline of the division of power among them.

Within these broad parameters, scholars have offered a range of more specific definitions of federalism, and no universal agreement about the term's precise definition has been reached. Different definitions produce somewhat differing classifications of political systems into federal and nonfederal categories. The result is that the term 'federal' can be applied to a variety of political systems in which power is shared between general and constituent governments. The political institutions of ancient Israel and the Greek city-states displayed federal characteristics. The US federal system, established in 1789, has served as the prototype of modern federalism (Elazar, 1968). At the turn of the twenty-first century, significant federal elements existed in political systems across the globe, including Argentina, Australia, Austria, Belgium, Brazil, Canada, the European Union, Germany, India, Malaysia, Mexico, Nigeria, Pakistan, the Russian Federation, South Africa, Spain, Switzerland, the USA, and Venezuela (Elazar, 1994).

Among federal systems, there is variation in the degree and character of the distribution of power between national and regional governments. This variation can be observed both in formal constitutional arrangements and in the working relationships among different levels of government within a political system. One component of the variation between federal systems, and within individual systems over time, is the extent to which powers and responsibilities rest with the central government or with the regional governments. Federal systems also vary in the extent to which these powers are either strictly divided between levels of government or shared between those levels of government.

With respect to the first of these dimensions, scholars have not yet reached a consensus about a precise way to measure the relative centralization and decentralization of federal systems (Watts, 1998). The formal distribution of powers set forth in constitutions may provide some insight into the comparative degree of centralization between systems. Such a constitutional focus has limitations, however, and is unlikely to be as useful in measuring changes over time within a federal system. Here, close attention must be paid to legislative and judicial decisions altering the balance of power between the central government and the constituent governments. One summary measure that is commonly examined is the proportion of governmental expenditures undertaken by the central government, either in total or in particular policy areas (Peterson, 1995). Efforts to characterize variation in the distribution of powers between general and constituent governments in federal systems have also led to the development of a wide range of metaphors and conceptual models (e.g., 'dual federalism,' 'cooperative federalism'). These metaphors and models attempt to characterize either the degree of centralization in a federal system or the extent to which powers are strictly divided or cooperatively shared between levels of government, or both. In all, Stewart (1982) found more than 300 such models and metaphors that had been proposed in the literature.

Descriptive studies have also examined, both statically and dynamically, the mechanisms through which federal systems operate. Core areas of concern here include the constitutional, legislative, and judicial processes through which powers are allocated between levels of government, and the fiscal (e.g., grants-in-aid), regulatory, and political instruments through which governments within a federal system influence each other's actions (Wright, 1988).

Causal Approaches

The causal branch of the empirical study of federalism addresses two major areas of concern: the causes and consequences of the establishment and dissolution of federal systems, and the causes and consequences of changes in how powers are divided between governments within federal systems.

Federal systems can be established either by joining together previously independent governments, or by decentralizing power in a previously unitary state. The formation of federal systems involves somewhat different processes and conditions in each of these two cases. In all cases, however, federal systems emerge under political conditions that contain strong pressures for both political unity (in the form of a national government) and political autonomy (in the form of regional governments with meaningful powers).

The pressures for unity most commonly result from a desire for military or economic advantage that constituent governments feel cannot be achieved independently. When federal systems are formed from previously independent governments, the reluctance of these governments to cede too much power to a newly formed central government creates pressure for regional autonomy. More generally, pressures for autonomy most commonly involve protecting constituent governments' diverse interests, whether based on nationality, language, ethnicity, religion, economy, or other variables. Against the backdrop of these general dynamics, scholars have debated what conditions are necessary and sufficient to produce a federal system, with particular discussion of cultural, economic, political, social, and historical variables (Riker, 1975).

Scholars have sought to understand not only why federal systems are formed, but also what the consequences of federal systems are. For example, federal systems can have important consequences for the management of ethnic conflict, either mitigating or exacerbating ethnic tensions, depending on the particular institutional arrangements in place.

The late twentieth century witnessed the disintegration of some political systems that were federal in principle or practice, including the Soviet Union, Yugoslavia, and Czechoslovakia. The survival of federal systems is imperiled when institutional arrangements reinforce rather than crosscut existing lines of division within the system, or when one group or constituent government representing a supermajority dominates the overall system (Watts, 1998; Elazar, 1968).

At a less macroscopic level, the causal study of federalism focuses to a significant extent on the evolution of federal

systems: why the distribution of powers changes in federal systems, and with what consequences. There are numerous studies of the proximate impact of legislative, judicial, and executive decisions on the distribution of powers in federal systems. Other analysts have focused on the role of underlying forces such as changes in technology, culture, ideology, society, and economy (Anton, 1984).

In all, there is significant dissatisfaction among scholars with the current state of our ability to construct robust theories of why federal systems evolve in the ways that they do (Beam et al., 1983). Explanations focusing on proximate causes have been criticized for being atheoretical and for too often relying on single case studies. Analyses focusing on underlying causes have not produced a clear consensus (Anton, 1984). Understanding the causes of centralization and decentralization in federal systems will remain an important area of investigation in the decades ahead. Scholars may increasingly attempt to link explanations focusing on proximate and underlying causes, constructing theories that specify how underlying forces such as culture or economy might in turn produce centralizing or decentralizing actions by proximate institutions such as legislatures or courts.

Scholars have also discussed the consequences of centralization and decentralization within federal systems. For example, there is evidence that decentralized systems make decentralized political party structures more likely (Riker, 1975). In another realm, some scholars have argued that decentralization of redistributive and regulatory functions may lead to a competitive spiral in which subnational governments reduce their interventions in these areas (Peterson, 1995).

Future Directions

Several areas of the study of federalism will likely be of particular importance in the first decades of the twenty-first century, as the literature continues to respond to important political developments. Scholars will be particularly interested in: the interaction between economic globalization and federal structures the emergence and evolution of supranational federal arrangements, including the European Union and the relationship between federal structures and the management of conflict in multiethnic political systems.

Editor's Note

Political scientists continue to debate the virtues of the federalist form of government and of federalism as a normative or ideological position. See Alison L. LaCroix, 2010; see also Daniel L. Rubinfeld and Robert P. Inman, 2014.

Female Genital Mutilation

Aud Talle, University of Oslo, Oslo, Norway

© 2015 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 8, pp. 5447–5451, © 2001, Elsevier Ltd., with an updated Bibliography section supplied by the Editor.

Abstract

Female genital mutilation (FGM) is a collective term for various surgeries performed on young girls while growing up, often performed as part of initiation rituals into adulthood. Other frequently used terms are female genital cutting (FGC) and female circumcision (FC). The article gives an overview of the practice: its extent and distribution, operation practices, historical roots, and cultural explanations. FGM is particularly widespread in northeastern Africa and in parts of eastern and western Africa. It is estimated that some 130 million women in the world today are genitally mutilated. The most common form of mutilation practice is clitoridecomy. During the last few decades large-scale immigration to Europe and the USA from African countries has extended the geographical location of the practice.

Female genital mutilation is a collective term for various surgeries performed on young girls, often done as part of initiation rituals into adulthood. Other terms commonly used are female genital cutting, female circumcision, clitoridectomy, infibulation or Pharaonic circumcision, excision, and *sunna*. Except for female genital cutting and female circumcision which also are general terms and used interchangeably with female genital mutilation, the other terms are more specific, indicating the particular type of operations being performed.

Extent and Distribution

Sources estimate that perhaps as many as 130 million women in the world today have been mutilated genitally (Toubia, 1995). Since relatively little extensive statistical research has been conducted on the topic, prevailing figures quoted tend to vary. Figures usually are derived from approximate population censuses from areas where mutilation is known to be practiced.

As a cultural practice, female genital surgeries are particularly widespread on the African continent and to some extent on the Saudi Arabian peninsula, but are only sporadically documented from the rest of the world. Instances of genital mutilation are reported from selected communities in the Middle East and from Muslim Malaysia. In Europe and the USA, clitoridectomy was until the 1930s medically administered in diagnosis of excessive masturbation, nymphomania, and hysteria (cf, e.g., Roheim, 1932; Bonaparte, 1953). Cosmetic surgery of enlarged clitorises and labia minora has been reported recently both from the USA and Europe (cf Walley, 1997). In Europe and the USA, female genital mutilation was primarily a single instance phenomenon and not a social convention. During the last few decades of the twentieth century, however, large-scale immigration to Europe, the USA, and elsewhere from African countries where genital operations are mandatory, has extended the geographical location of female genital mutilation (cf Lionnet, 1992)

In Africa, the practice of genital surgeries is contained to certain regions only, most notably to the northeastern and eastern parts of the continent, from Egypt in the north to Tanzania in the south and across the continent along the Sahelian countries from Ethiopia to Senegal. It is practiced in some 28 countries and by a wide variety and number of ethnic groups. The extent and type of surgical intervention as well as its cultural meaning and social context vary considerably making it difficult to generalize across the societies in which female genital surgeries are the norm. Female genital mutilation occurs among Muslims, Christians (particularly among Copts), as well as adherents of traditional systems of belief, among agricultural and nomadic peoples alike and in rural as well as urban communities. The highest regional concentration, that is, where a majority of women in a particular area are mutilated, is in Northeast Africa; in the Horn (Somalia, Djibouti, and Eritrea), across Ethiopia, and into northern Sudan and Egypt. In Somalia and northern Sudan female genital mutilation is almost universal (Gruenbaum, 1996). Elsewhere in Africa, genital surgeries as a cultural practice are scattered and alternate with ethnic affiliation, religious faith, economic class, and level of education. Within the same community, practices may even vary between subgroups and individual families, causing a situation where mutilated women live side by side with nonmutilated females.

As a general rule, where female genital mutilation is performed, male circumcision is also the norm. People themselves often draw a symbolic and social parallel between boys' and girls' circumcision. This is, among other things, reflected in a common term for the interventions in the local vernacular. While a number of societies in Africa and beyond practice male circumcision without cutting their women, the opposite, however, is never the case.

Operation Practices

Mutilation practices vary greatly. In some areas, such as Amharic Ethiopia, girls are operated upon within 40 days after birth, while in neighboring Somalia the operation usually is performed when the girls are between 6 and 8 years old (Hicks, 1993; Talle, 1993). In Kenya and Tanzania the girls are cut routinely just before puberty and often in association with

elaborate initiation ceremonies (cf Murray, 1974). In a few, relatively exceptional cases reported among others from West Africa, the surgery is performed after puberty. It also has been reported that married women who have defied traditions and remained unmutilated, in cases of barrenness have undergone the surgery after being married in order to promote fertility. Not only the girl's age, but also the surgical intervention, the performance context, and ritual elaboration exhibit substantial variations. In places in Egypt and among devoted Muslims in towns in the Sudan, for instance, only the prepuce or the tip of the clitoris is excised. This operation is referred to as *sunna* ('duty' in Arabic, i.e., to follow tradition). Surgically, *sunna* is the mildest form of mutilation and physiologically comparable to the removal of the foreskin at male circumcision. Although encouraged by religious leaders, health personnel, and opinion makers as a commendable mutilation form, it is still uncommon. What people label *sunna*, however, in practice is often really a clitoridectomy.

The most widespread form of female genital mutilation in fact is clitoridectomy, an intervention that implies removal of the whole or part of the clitoris, sometimes together with the *labia minora*. In the latter case the operation is also referred to as excision. Various forms of clitoridectomy-cum-excision are practiced from Senegal and Mauritania in West Africa, across Sahel to Egypt in the northeast, and southwards to Tanzania in East Africa. It is carried out across the whole area where female genital surgeries occur.

The surgically most severe form of operation is called infibulation (from Latin *fibulae*, clip) or Pharaonic circumcision. This is a form of surgery where the *labia minora* and parts of *labia majora* are excised wholly or partly, and often the clitoris; the sides of the vulva are then stitched together. A tiny orifice is left open serving as an outlet for urine and menstrual blood. The surgery transforms the genitals of a woman into a flattened, smoothed, and closed vulva with an oblong scar and a miniscule opening at the lower part. The practice of infibulation is particularly prevalent in the Horn of Africa, in the Sudan (Northern), and in southern (Nubian) parts of Egypt. It also occurs widely in Mali, in northern Nigeria, and among ethnic Somalis in other East African countries. The infibulated women are opened (defibulated) at marriage, either surgically – often by the practitioner who did the closing – or by the husband at penetration.

In medical and anthropological literature it is common to differentiate between four types of genital surgeries: *sunna*, clitoridectomy, excision, and infibulation. The types are classified by a gradient of surgical severity. Variations and modifications of the different types may occur over time as well in individual cases within the same geographical location. In the Sudan, for instance, an intermediate type, a compromise between excision and infibulation, sprung up during the colonial area as a local response to legislation against the practice imposed from outside (El Dareer, 1982). The skills and techniques of the practitioners as well as the preferences of individual families may contribute to variation and differences in mutilation styles.

Genital operations usually are performed in the home of the girl and, as a rule, undertaken by an elderly woman skilled in the task. Often these women are local birth attendants as well. In Somalia, the practitioners belonged traditionally to a ritually ambiguous and despised subclan within the community. In other places, and these days even in Somalia, any adult woman with the necessary courage and skills may engage in the practice.

The operation normally is performed without any extensive form of anaesthetic or antiseptic precautions. Different herbs, animal fat, dung, or other substances believed to have homeostatic and cicatrizing properties are applied to the wound after the operation to prevent excessive bleeding and infection. Depending upon the routine, skills, and preference of the practitioner, the instruments used for the surgery are either a small knife prepared for that kind of work, or a razorblade. In the case of infibulation, the severed parts are stitched with thorns of the acacia species, or recently, with catgut. In urban areas, medically trained personnel or paramedics commonly perform 'circumcision' on both boys and girls. In addition to giving prophylactic antibiotics and tetanus injections, the urban practitioners normally apply local anesthetics when operating. Many parents prefer these modern operations as they tend to reduce the pain and minimize adverse effects, such as hemorrhaging or infection from the operation. With the medicalization of the genital surgeries, men have also become involved in operating on girls. Traditionally, men operated only on boys, while women operated on girls. The same-sex pair of circumcizer and circumcized reflected the thinking of male circumcision as an analogy of female circumcision.

Among peoples in Kenya and Tanzania and in large parts of West Africa, the surgical intervention is associated with elaborate rituals of initiation into adulthood (e.g., Murray, 1974). In northeastern Africa, where infibulation is widespread, the operation, however, is not normally followed by any extensive ceremonial celebration. The operated girl is usually given a few presents and the family mark the day with some extra food and drinks, but the event is not a ceremony of great societal worth. In cases of physical cutting being part of some more significant rites of passage into adulthood, the waning of such traditions has not necessarily led to a decrease in the surgery itself. Instead of being part of a larger event, genital mutilation is now often a single act performed on girls at almost any age.

Historical Roots

The existence of female genital mutilation dates back to pre-Islamic and pre-Christian time. Although the practice as such does not stem from religious affiliation, many people make an association between circumcision and religious faith. This is particularly the case in West Africa where genital surgeries both in men and women are more common in Muslim than Christian communities (Koso-Thomas, 1987).

The term Pharaonic circumcision originates from the folk legend that the pharaohs of ancient Egypt performed similar operations on their women. Whether the pharaohs actually infibulated their women or not will probably never be substantiated, but the term nonetheless indicates that we are dealing with a cultural phenomenon of great antiquity.

Greek merchants and travelers who crossed the Mediterranean in classical time mention that female genital mutilation occurred among Egyptians as well as among the peoples along

the Red Sea. The sparse descriptions emanating from these travelers, however, do not allow us to ascertain whether it was infibulation or clitoridectomy, or both, people practiced in earlier times.

European travelers visiting Egypt much later reported on the occurrence of clitoridectomy (Seligmann, 1913). However, female slaves from the south (perhaps Nubians from the Sudan or southern Egypt), whom the wealthy Egyptians favored as mistresses, were infibulated (Widstrand, 1964). Some authors held that these girls were mutilated upon arriving in the north by the slave merchants or by their masters to avoid loose living or unwanted pregnancies. This explanation is disputed as early reports suggest that infibulation occurred for some time among the peoples of the upper Nile in northern Sudan. Burckhardt who visited these areas early in the nineteenth century claimed that infibulated girls ('virgins') received a higher price on the Egyptian slave market than noninfibulated ones (Burckhardt, 1819).

The beginning of female genital mutilation remains obscure. It has not been possible to determine whether mutilation originated in one area and from there spread to other areas or whether it originated independently in various places. With reference to the African continent, however, it is not unlikely that the practice arose in a culturally, commercially, central area and from there reached and influenced other parts of the continent. This assumption is based upon the fact that the practice of female genital mutilation appears to have had varying historical origins depending when people came into contact with each other (cf, e.g., Murray, 1974). Historical and linguistic sources point to the Chusitic and Semitic-speaking peoples living along the Red Sea Coast as a core area of female genital mutilation (Seligmann, 1913; Hicks, 1993).

Recently, the practice of female genital mutilation is reported to have spread from one ethnic group to another in countries such as Chad, the Sudan, and Tanzania (cf Leonard, 2000; Gruenbaum, 1996). In the Sudan, lower hierarchy groups often assimilate the practice of mutilation in order to be able to marry those of higher rank. Young girls in Chad are reported to perform clitoridectomy as a mark of modernity; since around 1980 the operation has become a kind of fashion in at least one reported area (Leonard, 2000). Studies from places in West Africa suggest that the expansion of Islam is conducive to the spread of female genital mutilation. Among the ethnic Meru in Northern Tanzania, clitoridectomy has been revitalized as a sign of cultural pride and resistance against rapid modernization. These sketchy, contemporary examples show that the meaning of female genital surgeries may assume various values following shifts in social reality. To know its origin does not explain its present existence (Gruenbaum, 1996). One distinguishable trait in the spread of female genital mutilation, however, appears to be the copying of cultural practices of higher status groups by people of lower rank (cf Mackie, 1996).

The Cultural Explanation

The practice of female genital mutilation is embedded deeply in cultural and moral preferences, gender identity and person forming, perceptions of body aesthetics, and ethnic marking. The unsuccessful attempts made by the British colonial administration during the 1930s and 1940s to abolish or modify the most severe types of female genital mutilation in the Sudan and in Kenya testify to the social importance of the practice (cf Murray, 1974; El Dareer, 1982). Anthropologists and others often associate the tradition of female genital mutilation with a patriarchal social structure, practically and symbolically privileging female reproductive powers over female sexuality. (cf Boddy, 1982; Talle, 1994).

People themselves give many explanations to defend the practice. For instance, the pastoral Maasai of Kenya and Tanzania claim that a girl can neither be married nor give birth to healthy children if she is not clitoridectomized. Should she deliver before she is operated upon, the child will die or be born disabled (Talle, 1994). In the Sudan and Egypt, uncut female genitals are considered ugly and dirty. Men are reluctant to marry such girls because by not being 'purified' by genital excision, they are held to be immoral in the widest sense. For the Bantu-speaking Kikuyu in Kenya a girl must have her clitoris removed to be considered an adult and responsible person. And so on. People present a plethora of meanings and motives for upholding the practice. Although seldom elaborated on explicitly, the control of female sexuality is at stake. References to moral looseness, unmarriagability, and fertility failures speak strongly to the societal value of female chastity and of male control of female fertility and sexuality (cf, e.g., El Sadaawi, 1980; Gordon, 1991; Talle, 1993).

In Somalia, where the practice of infibulation is particularly widespread, the operation is performed in two stages: the excision and the stitching. First, the clitoris is excised. This is considered an act of purification (*xalaalays*; from the Arabic *xalaal*, allowed by religion). The clitoris (*kintir*) is a part of the body which is associated with dirt and childhood. A girl who has not been operated on is referred to as *kintirleey* (childish, i.e., having clitoris) and teased by peers. To adult Somali women the word *kinterleey* has a very negative and somewhat embarrassing ring. Another Somali synonym for *kintir* is *awle* which means approximately 'with (or having) father.' This term suggest that the Somalis, as a number of other peoples performing genital surgeries, see the clitoris as a male part in the female body and thus held to be unclean. When excised, women become more feminine (Talle, 1993).

Where infibulation is practiced, virginity is not held to be a natural condition in women but has to be forcibly implanted in girls while they are still young. The hymen of a woman, which attracts so much interest and attention in many other Muslim societies and evokes strong sanctions if broken before marriage, has little social or cultural significance among infibulation practicing people. To them a chaste girl means a 'sewn' girl. A tight infibulation is a sign of distinction and moral excellence. Symbolically, the closing is more important than the excision as the cutting of the flesh is irrevocable while the closing of the vulva can, in principle, be executed over and over again. Although never as tight as the first time, later surgeries (after childbirth and at divorce) return the woman's body to its previous state by remaking her virginity (El Dareer, 1982). Virginity under such circumstances is not an anatomical facticity but a social category (Hayes, 1975).

The closing of her vulva is looked upon as a protection for the girl against indecency and immorality. A reason often given,

for instance by Somalis, as to why originally they began to infibulate their girls was to prevent sexual assault of young girls while out herding alone. The infibulation, or the creation of the artificial virginity, is seen as a safeguard against unwanted pregnancies and unidentified paternity. Both in northern Sudan and in Somalia a nubile, 'virgin' daughter upholds and marks the moral standing of the partrilineal group (Hayes, 1975; Kennedy, 1970; Talle, 1993). To leave a daughter or sister 'uncut' is held to be unnatural; the vision of such a woman is beyond comprehension, something which cannot even be expressed in words.

A Global Concern

During the feminist wave of the 1970s in Europe and the USA, female genital surgeries became a politicized issue. At the Copenhagen conference in 1980 during the United Nations Decade of Women (1975–85) the issue was brought to widespread international attention. Opponents of the practice asserted that female genital mutilation was a severe abuse of women's and children's rights and demanded legislation against it. The term 'female circumcision' was substituted by 'female genital mutilation' (Hosken, 1982). This change of name from circumcision which is used for genital operations on men, was meant to draw attention to the severity of intervention, primarily in terms of health risks, on girls and women as compared with that of men (cf, e.g., Toubia, 1995).

Legislation against female genital mutilation is on the agenda of international organizations such as Save the Children, Amnesty International, WHO, UNICEF, and other UN agencies. To prevent the spread of such surgeries into their countries, European governments are passing laws criminalizing all forms of genital mutilation (cf Lionnet, 1992). African countries, Egypt, the Sudan, and Kenya among others, have also passed legislation against female genital surgeries.

The global discourse on female genital mutilation has often been moralizing, racially prejudiced, and without sufficient understanding of the social and cultural context of the practice. Many African women have reacted to the paternalistic attitude that often permeates the global debate. The term female genital mutilation, which has received widespread acclaim, but which holds the implicit assumption that parents and kin deliberately intend to harm children, is contested (cf Walley, 1997). A more neutral term proposed recently is 'female genital cutting' (Shell-Duncan and Hernlund, 2000). African women – themselves frequently victimized by genital surgery – have, however, also been among the strongest opponents to the practice (e.g., Abdalla, 1982). The latest voice in a string of personal testimonies of an excruciatingly painful intervention with lifelong suffering comes from an internationally celebrated Somali model, now a UN ambassador against female genital mutilation (Dirie and Miller, 1998).

Although opposition is growing everywhere, women continue to favor the practice. They do it not necessarily because they like it, but because they see no other alternative. Africans in exile, exposed to a majority society where mutilation is neither a norm nor an ideal and, additionally, relieved of the social pressure to perform it, may spearhead the eventual eradication of female genital mutilation.

Abstract

This article reviews theory and research on the increasing presence of women in management and examines how this affects gender inequality among subordinates. Whereas it is true that women in upper management are more likely to reduce inequality among subordinates, most female managers are located at the lower rungs of corporate hierarchies where they have little impact on prevailing patterns of gender inequality. We call for further research on the location of women in management hierarchies and how this could affect their careers of their subordinates.

Introduction

Theories of economic inequality have long implicated men's dominance of authority positions as a mechanism for the enhancement of gender inequality in the labor market (Kanter, 1977; Reskin, 1988). It is thought that men in power will hire, evaluate, pay, and promote subordinates in ways that benefit men and disadvantage women. This belief is so widespread that the term 'glass ceiling' has entered both popular discourse and scholarly writings, describing the dearth of women in leadership positions from which they could act to reduce gender inequality.

Whereas it is true that relatively few women are CEOs or sit on corporate boards, women have dramatically increased their presence in management. For example, in the United States, figures from the Current Population Survey (a monthly survey of the labor force) show that women's representation in management rose from just over one-fifth in 1975 to nearly half by 2005 (cited in Cohen et al., 2009: p. 320). Similarly, women account for over half of the managers and senior officials (including legislators) in many European countries, including Germany, Finland, and Denmark (see **Figure 1**). Yet, significant variation exists among the most developed countries, with Japan reporting lower female representation in high-status positions than many of the Middle Eastern nations including Qatar and the United Emirates. This indicates that high economic development does not equate to gender equality and identifies important country-to-country variation in women's status reflected, in part, through women's status on the labor market. Of course, given that government statistics often combine lower-, middle-, and upper-managers into the same occupational category of manager, it is difficult to determine whether women's increased presence in management represents real progress in ascending to authority positions within firms. A related question is whether once they are in power, female managers are able and willing to combat gender inequality in job assignments, pay, and promotions among their subordinates.

This article will review theory and research on women in management. We discuss the primary reasons why women have increased their representation in management and review findings on the impact that female managers have on gender inequality (specifically job segregation), pay inequality, and employees' well-being. We largely confine our review to the

Figure 1 Percentage of women in high-status positions by country (United Nations Development Report, 2009).

United States and Europe because most of the research on female managers has been conducted in these countries. We conclude with a call for additional research that will more clearly elucidate the effect that female managers have on gender inequality.

The Rise of Female Managers

In the United States, the feminist movement in the 1960s inspired trends toward managerial diversity. Universities increasingly responded to women's demands for inclusion by admitting them into previously male-dominated fields of study such as engineering, law, the sciences, and business. With the decline in the sex typing of college majors, the gender gap in college attainment similarly declined and by the early 2000s, rates of college graduation among young adults ages 25–29 years were higher for women than men (Cotter et al., 2004). As women upgraded their skills in previously male-dominated fields of study, they were well positioned to take managerial jobs, as they pursued their careers. In addition, more managerial opportunities were open to women as corporations diversified their managerial ranks in response to legislation mandating equal treatment of workers and policies that awarded government contracts to businesses that practiced diversity were in place.

Only in a stagnant economy would more female managers necessarily mean fewer male managers. However, over the last 50 years the economy did grow and newer industries emerged, especially in care work and service provision. The transition from a goods-providing economy to a service-providing economy has increased the number of low-wage and part-time jobs and has drawn more women into the labor force. It is plausible that men retained their managerial positions in industries where they had traditionally worked and that female managers were incorporated into care work and service industries, largely supervising other women who were low-paid and marginally attached to the labor force. Indeed, Stainback and Tomaskovic-Devey's (2009) analysis of company reports to the U.S. Equal Opportunity Commission showed that between 1966 and 2000, white men were over-represented (relative to their proportion of the labor force) in management in the old higher-paying industries, such as construction, manufacturing, and transportation/utilities, whereas women's gains in management were most pronounced in the newer lower-paying retail trade and personal and social service industries. Moreover, this study also found that the gender composition of the firm's payroll significantly determined access to management, in that firms with a higher percentage of female employees had proportionately more female managers.

The rise of female managers in Europe largely parallels that of the United States, albeit with important country-to-country differences. Indeed, the number of female managers globally has increased sizably but with rates plateauing since 2007 (Thornton, 2014). Further, women's managerial representation has not kept pace with women's participation in the labor force (Lyness and Terrazas, 2006). Yet, the European policy context varies greatly from the United States reflecting a long legacy of equal rights amendments. For example, the European Union adopted equal pay legislation in 1975 (Council Directive 75/117/EEC of 10 February) (Europa, 2014), followed by an equal access to employment clause in 1976 (Council Directive 76/207/EEC) (Europa, 2014). Clearly, Europe, headed by the European Union, has a long history of commitment to gender equality as reflected by legislation. Yet, the effectiveness of these policies, notably women's representation in managerial positions, varies by country. This partially reflects country-specific variations in the definition of managers (Vinnicombe, 2000). The segregation of female managers in Europe parallels that in the United States. Even in the most gender-equal countries where equal opportunity laws are strictly enforced, female managers cluster in the public and banking sectors (Adler, 1994). Finally, structural impediments also limit women's position in high-status jobs. Indeed, the female manager rates are often paradoxical to gender empowerment. In other words, women hold fewer than expected managerial positions in the gender-empowered countries. Two explanations are offered: first, gender role expectations frame women as being 'not serious' about work, which despite being merely a perception carries weight in promotion decisions (Catalyst, 2002). Secondly, the cost of generous welfare state provisions, notably long maternity leaves, prohibits the promotion of women into high-status positions (Vinnicombe, 2000; Thornton, 2014). This suggests that even strong anti-discriminatory policy provisions are not sufficient to overcome organizational gender inequality.

Turning our gaze globally, important variation in women's employment exists by region. Notably, South East Asia has some of the highest percentages of female managers (32%) ahead of Europe's mean of (24%) (Thornton, 2014). This, in part, reflects family processes – notably the reliance on the extended family for childcare that enables women's continuous employment. By contrast, patriarchal societies, including Japan, report some of the lowest rates of female managerial representation. In sum, women's global managerial representation reflects complex family, gender, and work dynamics.

Some are skeptical that the rise of female managers represents real progress for women. First, because of government oversight of their personnel practices, many US firms may have re-titled a 'glorified secretary' into an office manager in order to increase diversity in the ranks of management. Secondly, as service-sector organizations evolved over time, a process of title-inflation created many more lower-level 'managerial' jobs out of previously 'clerical' and 'administrative' jobs. Thirdly, women who did become managers (e.g., in government, education, and health care) were entering jobs vacated by men, who were increasingly entering more prestigious male-only managerial jobs (e.g., in financial and professional services) a process known as 'managerial re-segregation.'

Jacobs (1992) examined these arguments using census and survey data on managers between 1970 and 1988. Using the US General Social Survey, he found that three-fourths of female managers had subordinates, which contrasts with the 'glorified secretary' image of a female manager with no supervisory duties. Survey findings also showed that the jobs of female and male managers were similarly rewarding – only one-fourth of male and female managers "… would quit work if they had enough money." From the census data, Jacobs found that the integration of managerial jobs continued over time, in contrast to the argument that managerial jobs were re-segregating;

and he found no evidence that title inflation was reducing the standing of managers, as the manager/non-manager ratios in median pay held steady over time. On the other hand, Jacobs found that compared with men, female managers occupied the lower rungs on corporate job ladders; more than half of the men but only one-third of the women had subordinates who, in turn, supervised lower-level subordinates. And, perhaps most important, Jacobs reported that the gender pay gap among managers, although declining over time, was still larger than in the labor force as a whole. From these results, Jacobs concluded "… the predominant trend has been toward real, if slow progress into management on the part of women." This is an important conclusion because if the rise of female managers represents real progress toward gender equality, then these organizational leaders would be positioned to ameliorate gender inequality among subordinates. It is to that question that we now turn.

Do Female Managers Reduce Gender Inequality?

On the one hand, organizational demographic theory and research suggests that female managers act to reduce gender inequality in their work environments. Assuming preferences for in-group members, organizational demographers find that female supervisors evaluate and reward female subordinates more favorably (Tsui and O'Reilly, 1989). Others argue that boss–worker homophily is important in another way, as shared experiences with gender discrimination and work-family conflict increases the likelihood that female superiors will bond with and mentor female subordinates (Fagenson, 1993). Finally, homophily structures social and communication networks such that female subordinates gain access to more information, resources, and career-enhancing job assignments when they report to a female manager (Hultin and Szulkin, 2003).

On the other hand, research into segregation and status characteristics suggests that female managers have no impact on gender inequality. That is, female workers in general are stereotypically seen as less competent and more family-focused than men and will be crowded into occupations that pay less and have higher turnover (Ridgeway, 2011; Reskin, 1988). However, employers must secure the commitment of devalued female workers, especially in service industries where they may be in direct contact with clients and customers. Thus, firms assign female supervisors to those working in female-dominated jobs. This process of 'bottom-up ascription' sends a symbolic message to devalued female subordinates that mobility into management is possible for them via hard work and commitment to their employers (Elliott and Smith, 2001). If so, the gender pay gap among subordinates may have more to do with processes that segregate women into lower-paying female-dominated jobs and may be largely unaffected by the sex of supervisors.

Even at the upper reaches of corporate hierarchies, some question women's ability to reduce gender inequality. First, there is the tendency to 'think manager–think male,' so that even if women do ascend to management they are presumed to be less competent than male managers (Ridgeway, 2011; Schein and Müller, 1996; Wajcman, 1998). Not only must female managers outperform their male counterparts to gain recognition but corporate work cultures dictate that strivers work long hours and subjugate their personal lives to the business imperatives of their employers (Kanter, 1977). This further disadvantages female managers who, unlike men, are assumed to have domestic responsibilities that compete with work obligations. Thus, in a male-dominated corporate culture, female managers may have ascended to their positions because they distanced themselves from women's issues and refused to address gender inequalities among their subordinates. And, by 'managing like a man,' female superiors often earn the 'queen bee' label from female subordinates who are resentful that their female bosses do not do more to address gender inequality in the workplace (Wajcman, 1998).

Several studies report that female managers ameliorate gender inequality. For example, studies in the United States (Cohen and Huffman, 2007), Sweden (Hultin and Szulkin, 2003), and Portugal (Cardoso and Winter-Ember, 2010) all find that as the proportion of female managers rises in firms or in labor markets, the wage gap among subordinates declines. Another study shows that gender segregation within firms declines with female representation in management (Huffman et al., 2010); cross-national data (Lyness and Kropf, 2005) find that managers in gender-empowered countries (i.e., with a higher percentage of female managers in the labor force) are more likely to report the importance of work–family balance and be willing to offer employees flexible work arrangements. It is important to note, however, that most of these studies use hierarchal modeling techniques, showing that the size of the gender wage gap among individuals is conditional upon women's representation in management in the corporate or labor market. Because these studies do not directly link individuals to managers, their results may be spurious if some other factor (e.g., government oversight, firm size) explains both women's representation among managers and higher pay for employees.

When studies directly link subordinates to the sex of supervisor, the results tend to support the proposition that female managers are powerless to reduce gender inequality. In samples of small businesses (Penner and Toro-Tulla, 2010) and retail grocers (Penner et al., 2013), the gender gap in pay was unrelated to the sex of the owner or store manager. Further, in a survey of the US labor force, Maume (2011) found support for a 'queen bee' female manager effect, in that male (but not female) subordinates reported more job-related support and were more optimistic about their promotion chances when they reported to female supervisor. One potential criticism of these studies is that by asking subordinates to report on the sex of their supervisors, they are largely reporting on first-line supervisors, not upper-level managers who have more power to ameliorate gender inequality within the firm. Indeed, in a survey of Korean workplaces, Stainback and Kwon (2012) found that sex segregation in job assignments declined with women's representation in upper management but female representation among first-line supervisors was associated with higher levels of sex-segregated job assignments among subordinates. In effect, highly placed female managers acted to reduce gender inequality but sex segregation among subordinates generated sex-segregated supervisory roles.

Summary

If female managers are to reduce gender inequality in the labor market, they must first gain access to powerful positions within firms and then act upon their desire to hire, pay, and promote female subordinates, similar to the existing position with regard to men. In this article, we have found that research on female managers is growing but the evidence on these two propositions is equivocal. First, in regard to access to management positions, the literature quite clearly implicates government efforts to promote equality as an impetus to women's increased presence in management. Yet, men have retained their management positions in the older male-dominated higher-paying manufacturing and financial service sectors of the economy, whereas women have increasingly gained access to management in newer female-dominated and lower-paying personal, trade, and social service sectors of the economy. Second, in regard to their effect on inequality when women manage, the evidence does not resolve the question of whether female managers act as 'change agents' or are 'cogs in the corporate machine.' Ecological studies report that women's managerial representation at the firm level reduces wage inequality at the level of subordinates; but when studies directly link sex-of-supervisor with subordinates, the wage gap is unaffected and there is even some indication that female superiors foster men's careers at the expense of their female subordinates. But ecological studies are plagued by concerns about spuriousness and the 'null sex-of-supervisor effect' on the gender wage gap of subordinates is likely because these studies are only observing first-line supervisors; if samples had more workers reporting to upper managers, the findings may be more supportive of the proposition that female managers are change agents.

In the end, the salient question may not be whether female managers matter in ameliorating inequality, but rather how their effectiveness varies across industries and the organizational context. Where women are represented in upper management, their presence and policies appear to reduce gender segregation and the gender pay gap. Yet, women's representation in the ranks of lower- and middle-managers appears to be an organizational strategy to match supervisors to workgroups that are largely female and poorly paid. From these lower-level supervisory positions, women have little power to affect change and reduce inequality. This returns us to the question of whether women's presence in management represents real or vacuous progress toward gender equality. Jacobs' (1992) conclusion that the rise of female managers represents slow but steady progress toward equality is more than two decades old and there is clearly a need to further investigate women's location in contemporary corporate hierarchies. This is especially true in light of research by Cohen et al. (2009), which drew on US census data to show that among managers, sex segregation increased between 1990 and 2000. This suggests that in contrast to past trends toward integration, managerial jobs were in the process of a re-segregation that allocated the poorest managerial jobs to women and the best managerial jobs to men.

We suspect that macroeconomic trends may be responsible for this process of managerial re-segregation. Beginning in the 1970s but accelerating in the last two decades, the 'service-oriented' employers have altered the employment relationship by hiring more contingent and part-time workers, freezing wages, and downsizing and reorganizing their work operations (Kalleberg, 2009). If women managers are over-represented in industries that employ low-wage and contingent labor whereas male managers are found in high-wage industries with stable workforces, then women's status as managers vis-à-vis their male counterparts may have eroded in the last few decades. This is a clear clarion call for further research on the relative position (and rewards) of male and female managers.

Finally, nearly all of the research cited above is cross-sectional in design, leaving open the question of how career trajectories are affected by male versus female managers. More clearly identifying the organizational actors affecting the decisions (hiring, job assignment, pay, promotion, etc.) that impact gender inequality and by observing how these vary over the course of a career is needed in future research. This will require difficult and ambitious data collection efforts but such projects are necessary if we are to better understand how and in what organizational context, female managers ameliorate gender inequality among subordinates.

Female Quotas in Parliament: Do They Make a Difference?

Mona L Krook, Rutgers University, New Brunswick, NJ, USA

Abstract

Electoral gender quotas have emerged as widespread political reform in recent years, having been adopted in more than 130 countries worldwide as of 2014. This article presents an overview of gender quota policies and surveys their effects in five respects: numbers of women elected, legislative diversity, policy-making, public attitudes, and political engagement. Overall, the evidence suggests that the introduction of quotas has been important for rethinking the role of gender in political life, enabling women to play a greater role in politics around the globe. However, the impact of quotas on women's empowerment more broadly continues to be debated.

Countries around the world have witnessed dramatic increases in the proportion of women elected to national parliaments since the 1990s. These changes are due in large part to the introduction of electoral gender quotas, establishing minimum thresholds for the nomination of female candidates. Although the first quotas were adopted in the 1930s, these policies became increasingly popular in the 1990s and 2000s in all major regions of the world (Dahlerup, 2006; Krook, 2009). The recent and global nature of these developments has sparked both scholarly and popular interest, leading work on quotas to become the fastest growing area of research on women and politics (Krook, 2006b), as well as a key focus of the gender-related programing of international organizations (Krook and True, 2012; Towns, 2010). Quotas have become the subject of a rich and expanding literature, with the potential to affect how social and behavioral scientists study a host of questions related to elections and political representation.

Gender Quotas

Gender quotas constitute the widest-reaching electoral reforms in recent years. Between 1930 and 1980, only 10 countries established quota provisions, followed by 12 states in the 1980s. Over the course of the 1990s, however, quotas appeared in more than 50 countries and have been joined by more than 50 more since the year 2000 (for an updated list, see http://www.quotaproject.org). As a result, quotas now exist in more than 130 countries around the world, but the vast majority of these measures have been passed within the last 15 years. The main reasons given for quota adoption include the mobilization of women's groups, the strategic incentives of political elites, and the support of international organizations and transnational networks (for a review, see Krook, 2009). One of the few countries where these debates have seen no echoes is the United States, where there is strong normative resistance to mechanisms of affirmative action and little pressure to conform to emerging international norms. In addition, the system of primary elections employed in the United States makes quotas for women especially difficult to apply (Krook, 2006a).

The three main types of quotas are reserved seats, party quotas, and legislative quotas. *Reserved seats* involve reforms to constitutions, and occasionally electoral laws, which set aside seats for women. They are found in Africa, Asia, and the Middle East. Although they first emerged in the 1930s and were the main type of quota adopted through the 1970s, since the year 2000 they have been passed in various countries that otherwise have very few women in politics. In most instances, they provide for low levels of female representation, usually between 1 and 10% of all representatives, although since 2000, several countries have instituted much larger provisions of 30%. In some cases, like India, reserved seats apply to single-member districts in which only women may run for election. In others, such as Afghanistan, they are allocated in multi-member districts to the designated number of women that win the most votes. In yet others, like Uganda, women are selected to these seats several weeks after the general elections by members of the national parliament.

Party quotas, in contrast, entail voluntary changes to party statutes committing a particular party to aim for a specific proportion of women among its candidates. They were first adopted in the early 1970s by a small number of socialist and social democratic parties in Western Europe. Over the course of the 1980s and 1990s, however, these measures began to appear in a diverse array of parties in all regions of the world, such that today they are the most common type of gender quota. They typically set a goal of between 25 and 50% female candidates. All the same, the phrasing of this requirement varies: some policies identify women as the group to be promoted by the quota, for example in Argentina, South Africa, and Spain, while others set out a more gender-neutral formulation, as in Italy and several Nordic countries. Party quotas govern the composition of party lists in countries with proportional representation electoral systems, which is the case in much of the world, and are directed at collections of single-member districts in countries with majoritarian arrangements, such as the United Kingdom.

Legislative quotas, finally, are measures enacted through reforms to electoral laws and sometimes constitutions requiring all parties to nominate a certain percentage of female candidates. They tend to be found in developing countries, especially Latin America, and postconflict societies, primarily in Africa, the Middle East, and Southeastern Europe. They are the newest kind of gender quota, appearing first only in the 1990s. They generally call for women to form between 25 and 50% of all candidates, and in most instances, the language of these

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64064-3

measures is gender-neutral, speaking of women and men together or making reference to the 'underrepresented sex.' Yet, legislative quotas vary in terms of how strictly their goals are articulated: some speak vaguely about 'facilitating access,' as is the case in France, while others offer concrete guidelines regarding the selection and placement of female candidates, like in Argentina, Belgium, and Costa Rica. Similar to party quotas, these policies are implemented in different ways depending on the electoral system, applying alternatively to party lists, the case in much of the world, or to a broader group of single-member districts, as in France. However, given their status as law, a distinctive feature of these quotas is that they may contain sanctions for noncompliance and be subject to oversight from external bodies, as in Mexico and Portugal. Quotas are therefore subject to extensive within- and across-category variation, in addition to being adopted for a range of different reasons.

Numbers Elected

One of the puzzling features of quota policies is that they have not resulted in a uniform rise in the proportion of women elected: some have produced dramatic jumps, while others have led to more modest changes and even setbacks in women's representation (Krook, 2009). In addition to differences in the features of specific policies, which affect their likelihood of being implemented, cross-national comparisons are complicated by the fact that quotas are introduced when variations already exist in the percentage of women in national parliaments. Outcomes are thus the combined result of quotas, where these are present, and other factors that were at work before quotas were established. As a result, quotas do not simply lead to gains proportional to the quota policy, but also interact in various ways with features of the broader political context.

Three reasons have been offered to untangle these effects. The first concerns the details of quota measures themselves. Although reserved seats guarantee changes in the numbers of women elected, some claim that party quotas are more effective than other types of quotas because they are voluntary measures, adopted from concerns about electoral advantage. Others insist that legislative quotas have more force because they bind all parties, not simply those who choose to adopt quotas, and are enforced by state bureaucracies and the courts, rather than party leaders (Jones, 1998; Tripp and Kang, 2008). However, the impact of particular policies also stem from their wording, requirements, sanctions, and perceived legitimacy, all of which may have intended and unintended effects (Krook, 2009). In France, for example, the financial penalties associated with the 50% quota law create distinct incentives for parties of different sizes: larger parties tend to ignore the requirements, while smaller parties are more likely to comply, for the simple reason that the latter are under greater pressure than the former to maximize the amount of state funding they receive (Murray, 2007).

A second explanation relates to the 'fit' between quota measures and other political institutions. For example, quotas often have the greatest impact in countries with proportional representation electoral systems with closed party lists and high district magnitudes (Jones, 1998; Schwindt-Bayer, 2009). In Sweden, for example, multiple seats are available in each constituency and candidates are elected from lists put forward by political parties. In contrast, it is more difficult to apply quotas where only one seat is available per district, unless the quota entails reserved seats, as in Tanzania. Quotas also tend to improve women's representation in countries where several parties coexist and larger parties respond to policy innovations initiated by smaller parties, as well as in parties with left-wing ideologies where the party leadership is better able to enforce party or national regulations (Kittilson, 2006). Further, quotas are often more successful in countries where the political culture emphasizes sexual difference and group representation, and less successful where it stresses sexual equality and individual representation (Krook et al., 2009). In part, this is because quotas have been challenged in some countries as a violation of constitutional principles of equality, as was the case in Italy and the United Kingdom in the 1990s and Mexico and Spain in the 2000s.

A third and final account points to the role of various actors vis-à-vis quota implementation. Party elites, who are often overwhelmingly male, are the group most directly responsible for variations in quota impact, since the effective application of quotas largely hinges around elites' willingness to recruit female candidates. In a large number of cases, elites take various steps to mitigate quota impact, ranging from passive refusal to enforce quotas to more active measures – including large-scale electoral fraud – to subvert their intended effects. Elites in Bolivia, for example, went so far as to change male names in female ones as a means to circumvent the 30% quota law. However, other actors may play a direct or indirect role in enforcing quota provisions, including women's organizations inside and outside parties, national and international courts, and ordinary citizens, all of whom may monitor party compliance with quota measures in ways that lead elites to ignore or honor, and possibly even exceed, quota requirements (Krook, 2009). Policy design, fit with other electoral institutions, and the presence or absence of political will to implement quota provisions thus all play key roles in shaping the effects of quotas on women's opportunities to be elected.

Legislative Diversity

Although increasing the numbers of women in political office is a central focus of quota reform, a closer look at the debates surrounding quota adoption suggests that their spread is not simply linked to concerns to increase women's political presence. Supporters argue, for example, that such measures will increase diversity among the types of women elected, raise attention to women's issues in policy-making, change the gendered nature of the public sphere, and inspire female voters to become more politically involved. At the same time, opponents express concerns that quotas will facilitate access for 'unqualified' women, bring individuals to office with little interest in promoting women's concerns, reinforce stereotypes about women's inferiority as political actors, and deter ordinary women's political participation (Franceschet et al., 2012). In other words, quota campaigns revolve around competing claims about what quotas might 'do' if enacted,

suggesting that quotas may have a host of positive and negative effects, above and beyond their impact on the numbers of women elected.

One common debate regards the types of women who might be chosen via quotas: advocates propose that women from more diverse backgrounds will be elected, while opponents express concerns about elite and 'unqualified' women benefiting from quota provisions. The findings thus far reveal a mixed picture, tied at least in part to difficulties in defining 'qualifications' for political office. Moreover, there can be tensions in the preferences of different constituencies: whereas women's movements might hope that the women elected via quotas more closely resemble 'ordinary women' and/or have feminist credentials, political elites might opt for female candidates who are more similar to the men already in office on the grounds that these characteristics conform with their already existing criteria of 'merit' (Franceschet et al., 2012).

Some studies indicate that quotas lead to the recruitment of elite women, especially those with ties to powerful men, and women with close loyalties to their parties (Cowley and Childs, 2003; Goetz and Hassim, 2003). Definitions of 'elite,' however, may also include women with high educational attainment, which, by some measures, would suggest high levels of qualification (Sater, 2007). Other research finds that quotas promote greater diversity in candidate selection, with those benefiting from quotas being relatively young and often coming from marginalized groups (Hughes, 2011). Almost all studies observe, in one way or another, that the women who accede to office via quotas have less overall political experience than their nonquota counterparts, both male and female. While this might be taken as evidence that quota women are less 'qualified,' it might also be viewed in terms of women's exclusion from electoral politics not affording them the opportunity to accumulate similar levels of political experience (Murray, 2010). Further, many of these women bring with them backgrounds in community organizing, suggesting that women may simply have different kinds of political experience (Franceschet et al., 2012).

Policy-Making

A second set of claims put forward during quota campaigns relates to how quotas might shape the legislative behavior of women in parliaments, above and beyond the effects of sex and gender. Most supporters make their case for quotas on the grounds that politics would change as a result of women's increased inclusion. They argue that policy-making would shift as a result of women's distinct policy priorities and, by allowing new voices into policy debates, would foster enhanced democratic legitimacy and good governance. Because women elected via quotas are elected because they are women, these debates may trigger a 'mandate effect,' leading citizens to anticipate that quota women are more likely than their nonquota counterparts to promote women's concerns. At the same time, however, negative connotations surrounding quotas may also generate a 'label effect,' leading women elected via quotas to ignore women's issues – or face stigmatization by other legislators due to their mode of selection, undercutting their legislative initiatives (Franceschet and Piscopo, 2008).

Initial research lends support to both of these intuitions. On the one hand, women elected through quotas have reported feeling obligated to act for women as a group, which has inspired them to bring new issues to the political agenda (Schwartz, 2004). On the other hand, others have sought to disassociate themselves from the quota and women's issues to demonstrate that they are 'serious' politicians (Childs, 2004). At the same time, many have been accused of acting only as proxies for male relatives and of being excessively loyal to party leaders (Goetz and Hassim, 2003). Both of these trends – deliberate lack of attention to women's issues and blind adherence to the policy priorities of political sponsors – lead to inattention to women's concerns in the policy process.

These dynamics, however, are again rooted in women's lack of presence in the political sphere. When quotas are introduced in a context where women have largely been absent, and especially where political life is governed by dynamics of patronage, quota women often do not have the skills or resources that would make them less vulnerable to manipulation (Cornwall and Goetz, 2005). In some cases, further, quota women may need to tread carefully in response to harassment, intimidation, or security concerns (Wordsworth, 2007). Despite these negative findings, there is some evidence to suggest that quota women are making a difference 'behind the scenes,' proposing more and more bills related to women's rights (Franceschet and Piscopo, 2008), participating disproportionately in debates on issues concerning women (Wang, 2013), and lobbying ministers and party leaders to pursue women's rights initiatives (Cowley and Childs, 2003).

Public Attitudes

A third and fourth group of assertions made during quota debates concerns the broader meaning of quotas for gendered ideas about the 'public' and the 'private.' As feminist theorists have long noted, men have tended to be associated with the public sphere of the economy and politics, while women have often been relegated to the private sphere of the home and family (Elshtain, 1981). The power of this divide has meant that women's movements have needed to mobilize in order to open up access for women to public sphere activities, including work and politics, which have traditionally been viewed as 'male' spaces. In such a context, quotas may serve an important symbolic purpose in legitimizing women as political actors, overcoming enduring gender gaps in women becoming candidates and elected officials. Opponents contend, however, that quotas may instead prove to be counterproductive: through 'artificial' solutions, quotas may reinforce negative stereotypes about female politicians as not belonging in politics or being able to make it there 'on their own.'

Some evidence bolsters the view that quota introduction may alter traditional gendered views about women in political life. A series of studies on India indicate that exposure to female leaders as a result of quotas can weaken gender stereotypes, eliminating negative bias in how the performance of female leaders is perceived, especially among male constituents (Beaman et al., 2009); enhancing the electoral prospects of women once seats are no longer reserved for women (Bhavnani, 2009); and even altering the aspirations

and levels of educational attainment that parents envision for their daughters (Beaman et al., 2012). Focus groups in Rwanda reveal, along similar lines, that gender quotas have led to a broader transformation in citizens' relationships in the private sphere, empowering women within their families as well as communities (Burnet, 2011).

Other work finds, however, that outward acceptance of the legitimacy of quotas often masks continued resistance. This is perhaps most obvious in the failure to fully implement quotas, whether these are state- or party-mandated (see above and Hinojosa, 2012). Resistance to quotas, however, may also take on less overt forms. Research finds, for example, that even years after quota introduction, many male (but not female) elites still do not accept quotas, denying the role of structural patterns of discrimination in favor of attributing female underrepresentation to choices made by individual women (Meier, 2008). Others simply 'forget' to implement quota policies, even when they do not openly speak out against them (Holli et al., 2006).

Political Engagement

Another way in which quotas may contribute to the erosion of the public/private divide is by inspiring female citizens to get more politically involved. As a signal that politics is open to women, these policies may, for example, lead women to turn out to vote, engage in protests, or discuss politics with friends at greater rates than prior to quota adoption, as well as provide new role models that lead them to put themselves forward as political candidates. On the flipside, skeptics suggest that the ongoing controversies surrounding quotas may serve instead to reinforce negative stereotypes about female politicians and thus further discourage women's political participation (Franceschet et al., 2012).

On balance, the evidence points to more positive than negative effects. Case studies indicate, for example, that quotas increase the rate at which female voters contact their political representatives (Childs, 2004; Kudva, 2003). Others find that the adoption of quotas has the effect of encouraging women to begin a political career, acquire political skills, and develop sustained political ambitions (Geissel and Hust, 2005). Still other work observes that quotas help build support for women's movement organizing more generally (Sacchet, 2008). At the same time, however, other scholars conclude that quotas have little or no effect on women's political activities, such as their willingness to sign petitions or participate in protests (Zetterberg, 2009). Even more troubling, some suggest that the presence of quotas may in fact be associated with the decreased strength (Britton, 2005) and increased repression of women's groups (Longman, 2006).

Conclusion

Gender quotas are a recent global phenomenon, taking diverse forms and reaching the political agenda for both feminist and nonfeminist reasons. Although women still do not occupy half of all seats in national parliaments (for up-to-date statistics, see http://www.ipu.org/wmn-e/classif.htm), a survey of global trends is encouraging: women appear to have shattered the political glass ceiling in countries with a diverse array of social, economic, cultural, and political characteristics. Quotas have played a key role in propelling these dramatic gains, interrupting existing dynamics of candidate selection that have tended to favor men over women. Quotas have not, however, always had their intended effects: the numbers of women elected in the wake of quota provisions has in some cases dramatically improved, while in others the level of female representation has stagnated and even declined. The broader effects of quotas also tend to be the subject of ongoing discussion, raising questions as to whether or not they empower women or make a difference in national political life.

More systematic research is needed in order to determine the effects of quotas on the election and empowerment of women. At least three new directions of research will be valuable in helping to parse out the conditions under which quotas might best serve women as a group – as well as contribute to positive social, economic, and political transformation in the countries in which they are introduced. One is to more closely consider questions of context: not only may quotas 'mean' different things across countries, but a variety of factors – age of democracy, level of development, and nature of party system, among others – may provide distinct opportunities and constraints for cultivating a diverse pool of representatives, promoting greater attention to women's policy concerns, and reorienting how citizens view women in politics and the political process more generally.

A second direction is to more explicitly incorporate the issue of time into quota analyses: a growing number of studies suggest that the impact of quotas may evolve from election to election, fostering more positive or negative effects over time. The conclusions drawn from one study may thus not generalize across all time points, with a broader time horizon being required in order to gauge how and why quotas have one impact as opposed to another at any given time. A third direction for future work is to address in greater depth the interconnections between different indicators of impact. The profile of legislators, for example, may shape the prospects to represent women's interests in policy-making – in turn shaping the symbolic effects of quotas on the public at large (see Franceschet et al., 2012). Gender quotas are thus likely to remain an important topic in social and behavioral research for a long time to come.

Finally, it is worth noting that quotas alone may not suffice to achieve gender equality in elected office. On the one hand, the application of quotas may be enhanced by programs expanding the pool of potential female candidates, supporting women's legislative capacities, and promoting broader transformation in public views toward women in politics. On the other hand, formal quotas may not be an option in all states and political parties, most often due to institutional barriers and ideological objections to the concept of positive action. Further, poorly designed policies can prove ineffective in achieving their stated goals. In these cases, alternative strategies are required to foster greater gender equality.

In contrast to the extensive literature on quotas, however, nonquota measures have not been subject to systematic documentation or research. Initial research suggests that actors on the ground in various countries have devised a number of

creative interventions for overcoming women's exclusion from political office, including public financing, political party initiatives, civil society programs, and parliamentary reforms (Krook and Norris, 2014). The sheer variety of these measures reveals a wide menu of options for promoting women in politics, while also underscoring the need for a multifaceted approach to tackle the multidimensional and diverse nature of obstacles to women's political inclusion.

Femininities

Abstract

Within the broad framework of heterosexuality, scripts of femininity operate as a way to organize gendered and sexual relationships between women and men. Girls and women learn to be feminine, and this socialization relates to interpersonal and institutional gender and sexual inequalities. The concept of hegemonic, or normative, femininity relates to masculinity constructs, as well as alternative forms of femininity marked by race, class, and sexual identity.

Scripts of Femininity

'Femininity' is a familiar term. Conversations about being feminine are common in everyday life and many people use the word 'feminine' to describe themselves and others. They may equate femininity with being a woman who embodies characteristics like being nurturing, sensitive, demure, or sweet. But femininity cannot be understood as a fixed set of essential traits that characterize all women. As a scholarly concept, femininity can carry diverse meanings with numerous interpretations. Within the context of heterosexual relationships, performances of femininity can employ different scripts. These scripts act as guidelines for individual behavior and social interaction. They are learned at an early age and reinforced throughout the life course.

When examined as a whole, individual expressions of femininity reveal distinct patterns. These themes become reinforced throughout different social institutions such as media, education, religion, sports, and the workforce. Studying these institutional or macrolevel forms makes it possible to see how ideas about femininity represent a much larger concept than simply wearing makeup and high heels while smiling coyly and sitting with one's legs crossed. Pulling back the conceptual lens reveals that femininity is a socializing ideology that defines and organizes material ways of life, particularly practices related to gender and sexual relationships. This ideological concept also casts some forms of femininity as hegemonic, or dominant, while marginalizing and subordinating other versions of femininity. These manifestations of femininity illustrate the varied ways femininities have been defined in Western cultures.

Learning to Be Feminine

Every child learns how to be a girl or a boy. The society in which a child is born contains plentiful information about how to express one's gender. These gender expectations are conveyed through numerous social institutions, such as media, law, and school. Gender socialization also occurs interpersonally, where family members, friends, and peers instruct children about appropriate gendered behavior. This process is known as the social construction of gender, and it gives meanings to words like girl/boy, woman/man, and feminine/masculine (Lorber, 1994).

When a young girl is taught how to act like a young lady, she is being taught the scripts of femininity. These messages reinforce what it means to be feminine, and, consequently, what it means to be a girl. In turn, boys receive a different set of messages about masculinity, which reference everything that a girl or woman is not. The social construction of gender relies on a binary gender system that positions men and masculinity as fundamentally different from women and femininity.

Each person then continues to 'do' gender throughout their lives, ensuring that they are signaling the right cues to be read as the gender they wish to present to others. Girls and women, then, do gender by demonstrating conventionally feminine characteristics (West and Zimmerman, 1987). Learning these femininity scripts is crucial for doing gender successfully. These scripts teach women and girls how to attract men's sexual attention. Consequently, the relationship between gender socialization and heterosexual relationships has been an important site for scholarly inquiry.

Theorizing Femininities

Scholars have illustrated how gender socialization and learning about femininity manifest in heterosexual relationships. They identify gender inequality as foundational in establishing relationships between women and men. Within most contemporary Western societies, hierarchical gender relationships shape much of social life. Male domination can be seen throughout social institutions like religion, science, and government. In this patriarchal context, women are subordinated to men. This gender stratification system also relies on conventional meanings of femininity, which include characteristics such as "physical vulnerability, an inability to use violence effectively, and compliance" (Schippers, 2007: p. 91). These defining features relegate femininity to a subordinate form compared to the more powerful construct of masculinity.

In some ways, gender scholarship has contributed to the continued subordination of femininity. Unlike the theoretical and empirical studies of masculinity, the concept of femininities has been undertheorized. Sociologist and feminist scholar R.W. Connell introduced the theoretical study of 'hegemonic masculinity' in 1987 (Connell, 1987), which sparked numerous theoretical and empirical studies that further illustrated, enriched, and solidified the concept as a paramount

feature of gender studies. Yet it took 20 more years before gender scholars dedicated similar analytical attention to the parallel concept of hegemonic femininity. Mimi Schippers first theorized about hegemonic femininity in her 2007 publication, 'Recovering the Feminine Other: Masculinity, Femininity, and Gender Hegemony'. In this work, Schippers describes hegemonic femininity as "the characteristics defined as womanly that establish and legitimate a hierarchical and complementary relationship to hegemonic masculinity and that, by doing so, guarantee the dominant position of men and the subordination of women" (Schippers, 2007: p. 94). This theoretical definition implicates femininity and women in hierarchical gender systems where hegemonic masculinity is continually able to sustain men's dominance over women.

In these conceptualizations of hegemonic gender expressions, men are expected to be powerful, strong, independent, and emotionally detached. A core component of hegemonic masculinity is men's desire for, and possession of, their binary opposite: the feminine object as embodied through women (Connell, 1987). Femininity is organized as antithetical to masculinity, and so is unable to embody the same characteristics without becoming stigmatized. In order to maintain men's dominance, the characteristics of femininity must not threaten the patriarchal gender order. Men who exhibit any indicators of femininity are ridiculed and negatively labeled as weak and womanly. Their exclusion from the hegemonic ideal results in marginalization and ostracism.

As ideological constructs, hegemonic standards of masculinity and femininity inform individual men's dominance over individual women, as well as the stratified patriarchal gender order as a whole (Schippers, 2007). By establishing characteristics of masculinity and femininity as binary opposites, where women and femininity are subordinate to men and masculinity, hegemonic constructs of these gender expressions form the basis for heterosexual interactions. This binary gender system of difference serves as the foundation for heterosexual erotic power within Western societies, where desire is thought of as resulting from attractions to difference. This heterosexual matrix functions as a natural consequence of the complementary and hierarchical relationship between masculinity and femininity, the meanings of which are constructed through these concepts of difference (Butler, 1990).

In the heterosexual matrix, conventional femininity is heralded as necessary for all women. A core assumption of hegemonic femininity is that women need to embody specific physical characteristics in order to successfully attract men. Within hetero-patriarchy, compliance with gender norms becomes vital and heterosexuality is compulsory (Butler, 1990). Women who seek men's attention must work to ensure they present an aesthetically pleasing amalgamation of face, body, dress, and mannerism. They may give in to a 'beauty myth' where, in order to possess adequate cultural or body capital, women need to conform to conventional standards of attractiveness (Wolf, 2002). The beauty myth is fueled by a profit-motivated industry that markets endless supplies of products designed to 'improve' one's natural appearance (Wolf, 2002). Women's pursuit and consumption of beautification technologies, such as plastic surgery and dieting, reflect cultural ideals about attractiveness and the feminine body. By attempting to embody these standards of attractiveness, women compete with each other for men's attention. These practices, with institutional support, reproduce a narrow version of heterosexual femininity as normative (Bordo, 1993).

Consequences of Upholding Femininity

Through institutionalized gender inequality, femininity becomes transformed as a material good expected from all women – but not without consequences. Women who do not conform to hegemonic femininity standards risk having their womanhood and sexuality questioned. Men, as well as other women, may view less feminine women as unattractive, lazy, apathetic, and lesbian (Wolf, 2002). Interpersonally, women who are less conventionally attractive are more lonely, less popular, and less sexually experienced than normatively attractive women. Compared to attractive women, unfeminine women are less likely to marry and less likely to marry men who belong to higher socioeconomic statuses (Sullivan, 2001). These stereotypes affect women's ability to connect with other women and men.

In addition to less rewarding personal relationships, less feminine women can also expect to experience significant losses in other central areas of life. In the workforce, women who are conventionally attractive are more often hired, promoted, and paid higher salaries than women who are perceived as unattractive (Sullivan, 2001). Within sports, women athletes often must display masculine traits such as competiveness, aggression, and dominance to excel in their games. Yet they face pressures to submit to a contrary sexualized discourse within sports that demands players embody femininity and heterosexuality (Mean and Kassing, 2008). The unforgiving arena of politics holds little compassion for women candidates, as exemplified in criticisms directed at Hillary Clinton for being too aggressive and unattractive and dismissals of Sarah Palin for being too sexy and dim-witted. Based on negative media representations, both of these high-profile politicians failed at straddling the precarious line of being assertive but not too masculine, and attractive, but not too feminine, when running for political office (Farmer, 2009). These institutional barriers inform the hetero-patriarchy that structures the gender stratification system.

Women often internalize these macrolevel messages. They may focus on maintaining an attractive outward appearance to garner approval from men and other women and to succeed in their careers. Yet a commitment to upholding normative standards of femininity can compromise women's physical and psychological well-being. Failure to comply with normative femininity can result in lower self-confidence, disordered eating, anxiety, and depression (Wolf, 2002). Thus, the dialectical relationships between cultural ideals of femininity and the practices women pursue to achieve them represent a systematic form of social control (Bordo, 1993). This social control of gender carries over into women's sexual relationships.

Femininity and Sexuality

Ideas about femininity, womanhood, and heterosexuality inform a person's sexual scripts. The concept of 'sexual scripts'

was first introduced in 1973 by John H. Gagnon and William Simon. These sociologists developed a theory of sexual interaction in response to biological explanations for sexual behavior that they deemed inaccurate (Simon and Gagnon, 2003). Gagnon and Simon believed that people negotiated sex and sexuality based on cultural messages, interactional cues, and internalized understandings, not biological urges or innate desire. They argued that social scripts shaped a person's sexual attitudes, behaviors, and identities (Gagnon, 1973; Gagnon and Simon, 1973; Simon, 1973; Simon and Gagnon, 2003). As gender and sexuality are intertwined, sexual scripts closely relate to constructions of femininity. Heterosexual women interpret norms about femininity and gender to negotiate their intimate relationships with men.

Gender inequality pervades much of social life and society's institutions, so it is inevitable that these dynamics will affect romantic and sexual relationships between women and men. Hegemonic femininity contributes to hetero-patriarchal imaginings of sexuality that render women submissive to men's desires. Just as women receive lessons about gender at a very young age, so too do they absorb how these femininity scripts relate to heterosexuality. Baby girls are often described as 'flirting' with boys and men who pay them attention, and girls learn early on that their (heterosexual) wedding day will be the best days of their lives. Research shows that adolescent girls consume media that emphasize looks and finding a boyfriend. Magazines marketed to teen girls showcase editorials and advertisements that advise readers how to be feminine and beautiful. Even though contemporary magazines pepper these messages with empowering rhetoric more so now than in past decades, the ends are the same: girls must be pretty and conventionally feminine to capture and retain men's desire (Gengler, 2011).

Research on young women's gender and sexual identities suggests that girls heed these media messages. Girls' body projects cater to the whims of male pleasure. Typically, girls need to give in to compulsory heterosexuality in order to forge successful gender and sexual identities. They police their own and other girls' bodies, desires, and behaviors to conform to hegemonic standards of hetero-femininity (Renold, 2000). Yet young women must be careful to avoid being seen as too sexually available, lest they be negatively labeled as sluts or whores. While teenage boys are often encouraged to actively desire sex, young women are expected to walk a fine line between being seen as sexually appealing but not acting in sexually promiscuous ways. This sexual double standard makes it difficult for young women to assert sexual agency and denies them gender equality in their intimate relationships (Tanenbaum, 2000).

Attempts to challenge the sexual double standard are not always effective. Girls who resist the idea that they should focus on appeasing male desire are only successful when they are able to demonstrate their heterosexuality (Renold, 2000). Similarly, teens who try to assert a postfeminist version of 'girl power' often can only do so in ways that bolster class-privileged, white, and heteronormative femininity (Allan, 2009). Thus, girls may mobilize sexual subjectivities through promoting neoliberal femininities (Charles, 2010). However, other research suggests that young women may challenge normative heterosexual scripts that require submission to men's desires. With a critical consciousness, young women may be able to assert agency through initiating sex, setting the terms of virginity loss, and openly communicating and acting upon their sexual desires (Stewart, 1999).

In adulthood, limited scripts of femininity often remain the same for heterosexual women. These women may sacrifice their own sexual desires and pleasures if they internalize messages that reinforce the sexual double standard (Crawford and Popp, 2003). Yet some adult women do try to project a sexual autonomy for themselves and their partners. Some women proudly claim a conventionally feminine appearance while also advocating feminist principles. They argue that women do not need to discard the trappings of femininity in order to challenge gender oppression (Stoller, 1999). Although these individual philosophies may be personally empowering, research suggests that they are insufficient to challenge the hetero-patriarchal gender order. For example, one ethnographic study on women's attendance at a strip club that featured male dancers found that the club's workers fostered heterosexist behaviors that diminished women's sexual autonomy. Although some women found the erotic space of the club to be a rare site for exhibiting their own sexual aggression, many did not (Pilcher, 2011). These disparate experiences illustrate that gender inequality in heterosexual contexts persists.

Feminine Sexual Bodies

Patriarchal constructs of binary gender also affect how people think about sexual bodies. Heterosexual sex is often framed as the penile–vaginal coital act that culminates with male ejaculation. This action positions women's sexual bodies as soft, passive, and compliant. Men use their harder, stronger bodies to penetrate women. They are thought of as acting on their more aggressive desires that must be fulfilled through orgasmic climax (Johnson, 1997). Women's vaginas are portrayed as receptacles to men's penises, instead of framing them as actively taking in hardness and ejecting flaccidity. One example of this paradigm can be seen in female genital cosmetic surgery. This procedure promotes reconstructing the vulva to accommodate men sexually. Yet it is often paradoxically marketed as sexually liberating for women (Braun, 2005). Such procedures increasingly medicalize women's sexual bodies, with healthcare professionals prescribing a range of treatments based on assumptions about women's desire. Treatments include off-label uses for drugs like Viagra, which are usually prescribed to men who seek relief from erectile dysfunction (Hartley, 2006). These surgical and medical interventions treat women's sexual bodies as passive objects of men's desires. They do little to understand the depth of women's sexuality or encourage whole-body approaches to sex that transcend penile–vaginal intercourse.

Rethinking Normative Hetero-Femininity: Race, Class, and Sexual Identity

In scholarship on femininities and heterosexuality, the influences of race, class, and sexual identity minorities are often mentioned, but not sufficiently developed. In response, some

scholars have chosen to articulate categorically specific theories and studies of non-hegemonic femininities that enrich current scholarship. These insights provide more nuanced understandings of marginalized communities.

Hierarchies of Race and Class

Hegemonic femininity reflects not only gender stratification, but hierarchies based on race, class, and sexual identity as well. Like hegemonic masculinity, the most privileged feminine gender expression is embodied by women who are also white, middle- to upper-middle class, and heterosexual. Alternative forms of feminine expression become constructed as inferior when they are believed to be more representative among women of color and women of lower socioeconomic statuses. Women in these communities may encounter negative sanctions for disrupting white expressions of femininity (Schippers, 2007). The conventional meanings of femininity as passive, dependent, and materialistic have been critiqued as representing white, middle-class women's values (Collins, 2000).

One alternative theoretical construction of femininity has been proposed by feminist theorist Patricia Hill Collins. In her groundbreaking work, *Black Sexual Politics: African Americans, Gender, and the New Racism*, Collins theorizes Black femininity. She illustrates how controlling images of Black women in media reflect racist stereotypes about Blackness. These images are also class-differentiated. Working-class Black women are portrayed in media as aggressive, domineering, and hypersexual, while middle-class portrayals evoke images of Black women as appropriately ambitious yet simultaneously subservient to white male authority. Middle-class Black women are also represented as more respectable sexually. These controlling images help justify racism and sexism against Black women. They promote a sexual politics of respectability that helps perpetuate gender inequality and partner violence in relationships between Black women and men (Collins, 2005).

Collins's ideas are supported in research that shows the effects of media messages on African-American preadolescents, especially within hip hop music and video media. For example, popular representations of Black women in these media influence youth to equate women's sexual desire with men's expectations (Stephens and Few, 2007). These images compromise a more autonomous sexuality among Black women. Yet some argue that it is possible for Black women to invoke these representations within Black culture to resist or challenge oppressive ideologies, as the forum of hip hop often mobilizes ideas of self-promotion (Collins, 2005).

Another alternative construction of femininities focuses on Asian American femininities. Research with Asian Americans reveals how women in this heterogeneous race group can internalize messages about the authority of normative white femininity, constructing Asian femininities as subordinated to the dominant version. In one study with Korean and Vietnamese Americans, these women used race as the primary basis for explaining what femininity meant to them. In white normative contexts, they felt pressure to submit to stereotypes about Asian American women as submissive and docile even though doing so disgusted them. In other situations, they felt compelled to distance themselves from stereotypes about Asian femininity in order to be taken seriously by dominant groups. Both behaviors subjugated Asian femininities to normative white standards of femininity, reifying the latter as hegemonic and personally ideal (Pyke and Johnson, 2003).

Overall, theoretical and empirical alternatives to hegemonic femininity have become more culturally available. They complicate normative representations of hetero-femininity. However, the increased visibility of different femininities does not always represent a positive shift in portrayals. Instead, representations within media often perpetuate race and class hierarchies. For example, one study on advertisements within the pages of teen girls' fashion magazines showed how the magazine equated beauty with whiteness, hypersexuality with Blackness, and technological skills with East Asians (Sengupta, 2006). These images reflected stereotypes about race and gender. In addition, media representations are not just abstract images; they can produce genuine effects in everyday life. One study on Latina women and media showed how Latina girls negotiated sexual agency within the complex realities of racism, patriarchy, poverty, and heterosexual privilege. In this study, some Latino families used media as a forum to initiate dialog about sexuality with daughters (Garcia, 2012). These race-based constructions of femininity offer a more complex understanding of hegemonic femininity.

Queering Femininities

Women who are not heterosexual have also proposed alternative femininity scripts that are useful to examine. In addition to expanding understandings of marginalized sexual communities, these scripts of femininity offer alternative visions of gender that include possibilities for heterosexual women who seek to challenge hetero-patriarchy.

Like femininity among heterosexual women, meanings of femininities vary among sexual minorities. For women who describe their sexual identities as lesbian, gay, bisexual, or queer (LGBQ), femininity can take on different meanings. Some feminine women who are sexual minorities embrace normative standards of femininity and internalize misogynist messages. Although these women may appear to meet hegemonic femininity standards, their sexual identities complicate the expectations of women who look conventionally feminine. Other LGBQ women, however, use their femininity in ways that try to reject both heteronormativity and heterosexism (Palder, 2008). Women who identify as 'femme' often seek to use feminine characteristics, or embody a hyperfemininity, as a source of power (e.g., Newman, 1995; Rose and Camilleri, 2002; Volcano and Dahl, 2008). Femme women invoke purposeful feminine expressions and assertive queer sexualities to challenge hetero-patriarchal male gazes. They resist viewing the trappings of femininity as inherently oppressive and argue that people of all genders can use femininity as a source of gender and sexual empowerment.

With a similar logic, popular writer, activist, and biologist Julia Serano asserts that femininity can and should be a source of empowerment for people, regardless of gender or sexuality. Writing as a transsexual woman, Serano proposes "putting the feminine back into feminism" (2007: p. 319). Serano denounces the hatred of femininity espoused within popular culture and by some feminist groups. She argues for a heterogeneous understanding of femininity that is decoupled from

femaleness. Her ideas 'queer' femininity by envisioning this form of gender expression and embodiment as potentially liberating for everyone.

Conclusions

Scholarship on femininity has contributed a wealth of knowledge to broader studies of gender and sexuality. As an ideological concept, hegemonic femininity theorizes the gender expressions and experiences of girls and women as learned. Institutions and individuals teach the scripts of femininity, and this education occurs throughout life as girls and women are socialized into conventional expressions of gender which treat them as distinct from, and subordinate to, the gender expressions of boys and men. The social construction of gender then reinforces binary classifications of gender which replicate gender inequalities. As a dominant form, hegemonic femininity also subordinates alternative versions of femininity, especially those marked by differences in race, class, and sexual identity.

These gender constructions are intimately connected to women's sexual relationships with men. The binary gender system serves as foundational for the hetero-patriarchal erotic matrix, where men continue to hold power over women. In this context, women compromise their own sexual agency to attract, please, and retain men. This dynamic creates a sexual double standard where women get punished for exhibiting a more active and desiring sexuality. Yet some scholarship suggests that women and girls do exact agency in negotiating sexuality, albeit with limited success. In addition, critiques from the margins of race, class, and sexual identity complicate understanding femininity as a monolithic, homogeneous form applicable to all women at all times. Future directions in the scripts of femininities will continue to complicate the interconnected relationship between gender and sexuality.

Feminism in Anthropology

Louise Lamphere, University of New Mexico, Albuquerque, NM, USA

Abstract

Feminism in anthropology in the United States emerged in the mid-1970s with the publication of two collections that examined women's subordination, power, and influence. By the 1980s, US anthropologists were rediscovering their feminist foremothers and turning their attention from only women to an analysis of gender. Feminists paid more attention to history, class, race, and sexuality as gender relations. Since 2000, feminists have taken a global perspective in studying immigration, sexuality, masculinity, new reproductive technologies, neoliberalism, and gender violence. Despite some claims that the twenty-first century is a postfeminist era, US feminist anthropologists are participating in a variety of activist movements and collaborating with feminists on other continents.

The 1970s saw the flowering of feminism within US anthropology. (Due to space limits, the author has confined this article to feminist anthropologists from the United States. The author has also not covered feminists whose specialty is either biological anthropology or language.) Influenced by the American feminist movement, women scholars, including professors, graduate students, and faculty wives, began teaching courses and delivering papers on women's roles in a wide variety of cultures. Two collections, published in 1974 and 1975, marked this new interest in women. *Woman, Culture and Society* (Rosaldo and Lamphere, 1974) coalesced around Michelle Z. Rosaldo, Jane Collier, and others at Stanford University and Louise Lamphere at Brown University. Another collection edited by Rayna Reiter (later Rapp) emerged from a number of feminist anthropologists at the University of Michigan (Reiter, 1975).

Many women in both of these networks were involved in the Vietnam antiwar movement as well as in the broader women's movement. They took part in consciousness-raising groups, testified at hearings on abortion rights, participated in rallies and marches, and attended conferences (Lamphere et al., 1997). Both collections focused on issues of equality and subordination and how to think about women's position cross-culturally. Feminists in other disciplines looked to anthropology to answer questions like, "Are women subordinate in every culture (as well as in our own)? Were there matriarchies where women ruled? Is there a biological basis for sex differences? And what is the role of the state in women's subordination? Analytical frameworks (structural, cultural, evolutionary, Marxist) reflected the graduate school training of many authors and many had not focused their field research on women's roles."

In 40 years since these two collections were published, feminist anthropology in the United States has changed. The number of feminist anthropologists has increased and diversified as the topics they study have multiplied. At least two new cohorts of scholars have conducted feminist research. More of these are minority women, men (both minority and white), women raised in non-Western traditions, and self-identified gay and lesbian anthropologists. Feminist anthropology has become international. Feminist analysis has blossomed especially in archaeology and in biological anthropology and linguistic anthropology. The emphasis has shifted. Gone is the focus on binary categories and sweeping universals. Writing about gender has replaced writing about women. More attention is paid to problematizing categories, attending to historic contexts, and experimenting with innovative writing strategies. Since 2000, feminist anthropologists are more engaged with issues of identity and difference, and the intersection of race, class, gender, and sexuality. Feminists speak about 'engendering' the discipline, and scholars have brought feminist perspectives to a wide range of topics such as globalization and transnationalism, new reproductive technologies, sexuality, gender violence, immigration, and the study of neoliberalism, the financial sector, and economic crisis.

Early Frameworks

The essays in *Woman, Culture and Society* emerged from a course at Stanford University in the Spring 1971, as well as papers delivered at the 1971 American Anthropological Association meetings, and the networks of the editors. The introductory essays by Rosaldo, Ortner, and Chodorow offered an integrated set of explanations for women's universal subordination of women, that is, in terms of social structure, culture, and socialization. All three argued that in every society women bear and raise children, and women's role as mother provides the basis for subordination. Women are confined to a domestic sphere (Rosaldo) or associated with nature rather than culture and seen as ambiguous, dangerous, and devalued (Ortner).

The Reiter collection also emerged out of a class, taught by women graduate students in 1971. Several articles reflected the four-field evolutionary and even Marxist orientation of the Michigan Department, in contrast to what many say is the structuralist and symbolic approach of the Rosaldo and Lamphere volume. Two articles had a lasting impact. Gayle Rubin's article "The Traffic in Women" pioneered the use of theory (Marx, Levi-Strauss, Lacan) to understand women's subordination and the creation of a normative heterosexuality. Reiter argued that the domestic/public divide coincided with the rise of the state. It was the first of several important treatments of women's subordination in relation to class divided, patriarchal states (Sacks, 1979; Silverblatt, 1987; Gailey, 1987).

The articles in both attested to the variety of positions women held in cultures throughout the world. Feminists offered examples where women held power or influence (McCormack, Brown) and case studies where women strategized to achieve their own goals even though men wielded power in patrilineal descent groups (Wolf, Collier, Silverman, Lamphere). Still others found cultures where men and women could be considered equal (Sacks, Gough, Draper). As Gayle Rubin put it "So they [the books] were locally inflected [structural and cultural versus materialist and evolutionary], but the project was a common one, and it was one of those historical tectonic shifts where you don't understand the forces that are impinging on all these different people in different places but they clearly were" (Lamphere et al., 2007: 417). Feminists felt, as Rapp said, "we and our whole generation were reconfiguring the field."

The three introductory essays in *Woman, Culture and Society* gave rise to a debate over women's subordination and the usefulness of dichotomies like domestic/public and nature/culture. Some scholars argued that in small-scale foraging and horticultural societies, women and men held roles that were "complementary but equal" (Schlegel, 1972). Working primarily from a Marxist perspective, Leacock (1980) (Eleanor Leacock was an important analyst of women's roles and mentor to feminists of the 1970s generation. In addition to her collected essays on women's status, she coedited collections on women and colonization and on women's work. She also published a critique of the culture of poverty and edited a new edition of Engels' *The Origin of the Family, Private Property and the State.*), Sacks (1979), and others took the position that colonialism had transformed and undercut many native economies, creating inequality where autonomy had been the norm.

The Turn to Gender, History, and Intersectionality

By 1980, feminists began to turn from 'finding women' to examining relationships the concept of "gender." Rosaldo's article "The Use and Abuse of Anthropology" (1980) was a first step in this direction. However, she continued to argue that women have been universally subordinate. She also began to break apart the categories o 'female' and 'male,' analyzing differences between unmarried young men and women and their married elders. Working with Jane Collier, she said "We are concerned to stress not the activities of women – or of men- alone; instead we are attempting to convey the ways in which a sexual division of labor in all human social groups is bound up with extremely complex forms of interdependence, politics, and hierarchy" (Rosaldo, 1980: 412). This same emphasis on gender and hierarchy is the unifying theme of *Sexual Meanings* edited by Sherry Ortner and Harriet Whitehead (1981). They call for an analysis of 'prestige structures' and suggest that gender systems are themselves prestige structures. Statuses such as warrior, statesman, Brahmin, or elder are seen as part of a male ranking system, while women get defined as wives and mothers, unmarked positions with lower prestige. These four authors pose models that are comparative and not based on universal dichotomies.

Micaela di Leonardo's collection *Gender at the Crossroads of Knowledge* (1991) represents this trend to examine gender rather than simply 'women.' In her Introduction, di Leonardo argues for a culture and political economy approach, one that respects many histories (rather than one evolution), takes a social constructionist position, and sees gender as embedded in larger institutions and other forms of hierarchy (race, class, ethnicity, and sexuality). Ann Stoler's historical analysis of the policing of sexuality in Indonesia and colonial Asia (Stoler, 2002), Patricia Zavella's comparative research on Hispana/Chicana women factory workers in California and New Mexico (1987; Lamphere et al., 1997) and Irene Silverblatt's work on women and the state in the Inca period (1987) are excellent examples of this approach to gender.

Discovering a Legacy

Simultaneous with the turn to gender and the importance of history, feminists began researching the lives of early female anthropologists and discovered a long lineage of women scholars and feminists. They reexamined the lives of well-known anthropologists like Ruth Benedict, Margaret Mead, and Elsie Clews Parsons and discovered the role of Franz Boas and the Columbia Anthropology Department in producing 20 women PhDs between 1920 and 1940. They recovered Nancy Lurie's history of the nineteenth-century Women's Anthropology Association outlining the beginnings of a female presence in the emerging discipline (1966). Several graduate students spearheaded the publication of *Women Anthropologists: A Biographical Dictionary* (Gacs et al., 1988), and *Hidden Scholars* (Parezo, 1993) examined the impact of women's research on the study of Native Americans in the American Southwest.

Adding to these sources that emphasize white women has been the new scholarship on minority women, many of whom did not have PhDs or spent their careers in minority institutions or outside the academy. One now views Zora Neale Hurston, Katherine Dunham, Ella Deloria, Christine Quintasket (Morning Star), Catherine Bond Day, Irene Diggs, Manet Fowler, and Vera Green as pioneering women in anthropology (Finn, 1995; Harrison and Harrison, 1999).

Full biographies have been written on a number of women anthropologists: Alice Fletcher, Elsie Clews Parsons, Ruth Benedict, Margaret Mead, Ruth Landes, Cora Dubois, and Zora Neal Hurston. These materials have made it possible for feminists to bring these women in from the margins and reevaluate their contributions (Lamphere, 2004). For example, Elsie Clews Parsons, Gladys Reichard, and Zora Neale Hurston can now be appreciated for their more dialogical writing that places the anthropologist within the text and creates more open, polyphonic descriptions of concrete interactions and conversations. Each used these textual strategies long before the appearance of the Clifford and Marcus collection (1986), often seen as the original call for a more dialogical approach to ethnography.

Diversifying Feminist Anthropology

The 1980s and 1990s brought many more minority and lesbian women into graduate programs anthropology and those who

obtained PhDs in the late 1970s began holding faculty positions. This laid the groundwork for a more diverse feminist anthropology. Johnnetta Cole's collection *All American Women* (1986) featured feminist writing and the biographic sketches of minority and working class women, as well as white women. African American feminists analyzed the impact of globalization and neoliberalism on women's lives in the Caribbean (Bolles, 1996; Harrison, 1997), collected the narrative histories of women (McClaurin, 1996), documented the impact of poverty (Mullings and Wali, 2000), and explored gender relationships in African cultures (Shaw, 1995). The forging of Black feminist anthropology is well documented in *Black Feminist Anthropology* (McClaurin, 2001). Among the Chicano/Latina woman who have studied women's lives are Patricia Zavella and Ruth Behar. Gina Perez, Monica Russel y Rodriguez, and Anna Ochoa O'Leary are among those who have made contributions during the first decade of this century. Bea Medicine's innovative scholarship on Lakota women warriors and Nancy Mithlo's research on Native American women artists are examples of contributions by Native Americans.

Another aspect of diversity has been the flowering of gay and lesbian anthropology. In the 1970s, this was initiated by Esther Newton's research on female impersonators, Ellen Lewin's (1993) study of *Lesbian Mothers*, and Elizabeth Kennedy and Madeline Davis's oral histories of lesbian women in Buffalo, New York. Ellen Lewin and William Leap have published three collections on the impact of gay/lesbian anthropology. *Out in the Field* narrates how gay and lesbian anthropologists negotiated their sexual identities during field research; *Out in Culture* emphasizes gay/lesbian theorizing; and *Out in Public* takes a reflexive public anthropology stance by exploring the ways both anthropologists and the gay/lesbian populations they study have engaged the public sphere and pushed for change.

Forging a New Theoretical Language

The important contributions of minority and lesbian feminists in the 1980s and 1990s cleared the way for a continued emphasis on what came to be called 'intersectionality,' the multiple interpenetration of gender, race, class, nationality, and other forms of difference. The attention to gender in relation to class and especially race owes much to the critique of white feminism by minority and Third World feminists often labeled as part of 'third-wave feminism.' The authors mentioned in the previous section are very much part of this same moment in theorizing gender.

The focus on intersectionality is also evident in studies of working class women, poverty and welfare, many influenced by Marxism and using a political economy approach. The collection *Women, and the Politics of Empowerment* (Bookman and Morgen, 1988) brings together feminist analysis of women's resistance, organizing and political consciousness in workplace, educational and community contexts across working class and minority communities. More extensive studies include Karen Sack's analysis of women hospital workers in *Caring by the Hour*, Ida Susser's focus on women in her New York ethnography *Norman Street*, and Mary Anglin's study of women's resistance in the Mica industry in *Women, Power and Dissent in the Hills of Carolina*. Two very excellent collections on women and welfare reform are edited by Catherine Kingfisher (*Western Welfare in Decline*) and by Francis Fox Piven, Joan Acker, Margaret Hollack, and Sandra Morgen (*Work, Welfare and Politics*).

In contrast to the political economy approach, postmodern feminists have followed the theories of Lyotard and Derrida who critique 'modernism' and its commitment of science, objectivity, and truth. However, many feminist anthropologists have been wary of a postmodern stance that dissolves the speaking subject and focuses primarily on discourse rather than on material reality (Mascia-Lees et al., 1989). Anthropologists remain committed to understanding the 'empirical reality' of women's lives and the analysis of social, political, and cultural structures. However, postmodernism has led feminist anthropologists to be conscious of the colonial heritage of their discipline, of their positionality as middle class observers and (often) white Western women. Many feminists have become advocates of critique, deconstructing our concepts as historically situated, culturally bound, and open to revision.

Several other trends emerged in the late 1980s, influenced by Marx, Foucault, Bourdieu, and Butler. First, Ortner (1989) drawing on the Marxist definition of 'praxis' and Bourdieu's concept of 'habitus' argued for an emphasis on practice or concrete actions emerging from structure that could also transform it (Ortner, 1989: 12). Second, anthropological feminists have used Foucaultian notions power as productive and capillary. Power, through structures like the panopticon, shapes the self and inscribes habits of self-policing and states of subjugation forming 'docile bodies' (Foucault, 1977). Aihwa Ong's study of Malaysian women factory workers (*Spirits of Resistance and Capitalist Discipline*), Ann Stoler's research on sexuality in Southeast Asia (*Carnal Knowledge and Imperial Power*), and Saba Mahmood's book on the Egyptian women's Mosque movement (*The Politics of Piety*) are some of the most important examples of this approach.

A third trend has been research on the body and embodiment. Studies by historians and feminist biologists have pointed to the Western bias in viewing the body and sexuality as biologically based, historically static, and as only situated in a two-sex, two-gendered fixed system. Rather than the body being 'presocial' and a blank slate, feminists using Foucault and Butler view sex and gender as malleable, culturally structured, and performative. Mascia-Lees and Patricia Sharpe's collection of essays exemplify this foray into analyzing the body in literature, painting, and contemporary US culture (2000).

Writing New Feminist Ethnographies

A central impact of postmodernist and Marxist theory has been the emphasis on rethinking the power dynamics embedded in feminists' relationship to their subjects. This began by interrogating the boundary any observer must confront – that between the Self and the Other, that is, between the investigator and those with whom she interacts. Feminist ethnographers questioned whether anthropology could be constructed differently when feminists study women. Stacey is deeply skeptical, stressing the class divisions and manipulative aspects of the feminist/subject relationship (1988). Marilyn Strathern

argues for an ambivalent relationship between feminism and anthropology since each mocks the way the contrasting discipline conceives of the Self/Other dichotomy (1987). However, Abu-Lughod is much more hopeful, suggesting that feminist ethnography can disrupt boundaries and replace the presumption of a universal female experience with a grounded sense of our commonalities and differences (1990: 27).

Other feminist anthropologists like Kirin Narayan and Patricia Zavella have explored the complexity of being partial 'insiders' (observers with kin or ethnic connections to those under study) yet being viewed as 'outsiders' because of national, class, and cultural differences. These essays recognize what Donna Haraway calls "situated knowledges" a feminist epistemological stance that acknowledges the social location of the researcher where knowledge is always partial and seen through the perspectives of active subjects (Haraway, 1991: 183–201).

This reevaluation has also led to different strategies for ethnographic writing. These include presenting women's voices in detail, including the author in narratives, and historically contextualizing ethnographic material. These writing strategies, also pioneered by Parsons, Reichard, and Hurston, move anthropology toward creating more dialogic rather than objectifying accounts. Lila Abu-Lughod's ethnography of Bedouin women's lives, *Writing Women's Worlds*; Ruth Behar's life history, *Translated Woman*; and Margery Wolf's *A Thrice-Told Tale* are examples of this growing trend.

The collection *Women Writing Culture* (Behar and Gordon, 1995) is in direct contrast to *Writing Culture* (Clifford and Marcus, 1986) that ignored feminism and women's writing. Several articles explore the writing of earlier women anthropologists, while other contributions attest to the women's past marginalization. There are also innovative examples of fiction, play writing, diaries, and narratives that suggest that feminist ethnography has taken new form and will reach broader audiences.

Engendering the Past through Feminist Archaeology

Feminist approaches to prehistory emerged more slowly than in social/cultural anthropology, but as they have grown, they have begun to transform archaeological theory and practice. *Engendering Archaeology: Women and Prehistory* (Gero and Conkey, 1991) is one of the first comprehensive responses foregrounding the analysis of gender. Contributors examine gender in a variety of archaeological contexts (e.g., pottery production, weaving, cooking, lithics, and art). The intention is to examine gender in relationship to power structures, household organization, the deployment of labor, and the organization of space.

Interest in gender continued to expand, but many archaeologists have been content with just "finding women in the past." In contrast, feminists examine gender relations and aim to change archaeological theory and practice. This means increasing the visibility of human agency, admitting the partial and situated nature of knowledge, and allowing for multiple interpretations rather than top-down, hierarchically positioned ones (Conkey and Gero, 1997: 429).

By the mid-1990s, there were a number of good examples of this new feminist research. Spector (1993) supplements her archaeological analysis of women's activities in a Wahpeton Village by using Dakota categories for found objects and engaging indigenous consultants. She also constructs an imaginative narrative of a how a woman's incised bone awl might have been made, used, and then lost. Elizabeth Brumfiel makes gender, class, and faction visible in her analysis of Azec figurines and tribute cloth (made by women weavers) (Brumfiel, 1996). Rosemary Joyce draws on Judith Butler's analysis of embodiment and subjectification to examine Mayan construction of gender as well as political hierarchy (Joyce, 2002), while Meg Conkey draws on feminist and indigenous archaeologies to explore domination in the archaeological record (Conkey, 2005).

The collection edited by Pamela Geller and Stockett (2007) contains articles that also take an intersectional approach by focusing on identity and difference, two themes that Geller emphasizes in her review (2009). A special issue of the *Journal of Archaeological Method and Theory* (Conkey and Wylie, 2007) brings together feminist thinking on archaeological fieldwork, practice, and theory. Articles also probe the 'backlash' by scholars of gender who wish to distance themselves from feminist approaches (Sorensen, 2000) and the continued reluctance by many (often male) archaeologists to acknowledge the contributions of feminists.

Emerging Issues in the Twenty-First Century

Since the 1990s, feminist anthropologists have become increasingly engaged with the study of the social issues that impact women in a globalizing world. Financial capital has become more mobile, production processes have moved to the Global South, and labor migration has increased. Worldwide computer networks and satellite connections as well as breakthroughs in biotechnology have transformed everything from television, film, and music to medicine, reproduction, and sexual norms. For anthropological feminists, the emerging issues of labor migration and women's work roles, reproduction and sexuality, gender violence, and human rights are all viewed through a global lens.

Gunawardena and Kingsolver's collection (2007) provides some important examples of how women's work is changing. From young factory workers in Sri Lanka to female traders in Ghana, domestic workers in Italy, and hotel workers in San Francisco, women are finding it difficult to make a living, but nevertheless forging survival strategies and contesting their situations. Migration is also gendered. Deborah Boehm shows how young Mexican males migrate to become adult providers while girl friends and wives remain to raise children or come to cook and keep house for a host of male relatives (2012) while Patricia Zavella's transnational study (2012) focuses on how Mexican migrant women and men struggle with displacement, instability, gendered racialization, and discrimination at work. Anthropologists are also studying the children of immigrants and their adaptation to the United States as well as women's role in helping their families hold on to language, customs, and identities (Coe et al., 2011).

International adoptions and the accompanying issues of culture and identity have been studied (Yngvesson, 2010; Howell, 2006). And as there are more immigrants from Middle Eastern cultures and Islamic states to European

Countries and to the United States, the maintenance of language differences, the veiling of women, and the practice of Islam have all become points of controversy (Abu-Lughod, 2008; Scott, 2007; Mahmood, 2005).

Feminist analysis of the body has also spawned an important literature within medical anthropology beginning with Emily Martin's *The Woman in the Body* (1987). *Conceiving the New World Order* (Ginsburg and Rapp, 1995) contains much of the new work on stratified reproduction across a wide range of countries from issues of abortion, assisted reproduction, and state controls on fertility to lesbian motherhood, single headed households, teenage mothers, and child care workers. Other book-length studies include Rapp's study of amniocentesis in New York, *Testing Women, Testing the Fetus*; Ragone's book *Surrogate Motherhood: Conception in the Heart*; Franklin's study on assisted reproduction, *Embodied Progress*; and Inhorn's ethnography of infertility in Egypt, *Local Babies, Global Science*. In the next decade, feminist anthropologists expanded their research on the new reproductive technologies and surrogacy to developing countries where their use and meaning are often very different (Rapp, 2011).

The body is also central to feminist and queer analysis of sexuality and sexual orientation an area that has grown and blossomed in the last two decades. Following on the ethnographies of gay and lesbian communities in the 1990s, more recent books, like those by Ellen Lewin, have focused issues of gay marriage and gay fatherhood. Others have continued the early work on gay and lesbian sexuality pioneered by Roger Lancaster in *Life Is Hard: Machismo, Danger and the Intimacy of Power in Nicaragua* and Evelyn Blackwood and Saskia Wieringa's collection, *Female Desire: Same-Sex Relations and Transgender Practices across Cultures*. Cymene Howe examines the gay and feminist movements in post-Sandanista Nicaragua (*Mediating Sexuality*) and Martin Manalansan portrays the lives of Filipino gay immigrants in New York (*Global Divas*). David Valentine examines the elastic term 'transgender,' (along with 'gay,' 'fem-queen,' or 'girl') in his book *Imagining Transgender* about the lives of those male-to-females in New York who see it as part of their identity, while Gayle Rubin's essays on sexuality (*Deviations*) and Margot Weiss' book on bondage (*Techniques of Pleasure*) explore bondage, discipline, sadism and masochism (BDSM) and alternative sexualities, theorizing about gender, hierarchy, dominance, and pleasure.

Anthropological studies of masculinity flourished in the 1990s with the work of Matthew Gutmann (*The Meanings of Macho*), David Gillmore (*Manhood in the Making*), and others. More recent research ranges from ethnographic analysis of male struggles with poverty, drugs, and race (Bourgois and Schonberg, *Righteous Dope Fiend*) to masculine images of colonial terror such as the pishtaco in Peru (Weismantel, *Cholos and Pishtacos*) to shifting definitions of masculinity in the Middle East that have emerged through the impact of new reproductive technologies (Inhorn, *The New Arab Man*). Mascia-Lees (2011) brings together all the major authors who have written on the diverse aspects of the body in a wide-ranging collection that sums up various approaches to embodiment from sexuality studies, to medical anthropology, to those interested in colonialism, racialization, and border politics.

The focus on globalization has encouraged the analysis of economic policy and institutions both at the high and low ends of the income spectrum. Feminists have written on neoliberalism and its impact on gender in Nicaragua (Florence Babb, *After Revolution: Mapping Gender and Cultural Politics in Neoliberal Nicaragua*), on the practices of governing and citizenship (Aihwa Ong, *Neoliberalism as Exception*), and on the creation of 'desiring subjects' with the appropriate needs, aspirations, and desires in China (Lisa Rofel, *Desiring China*). In the United States, financial crisis and income disparity have encouraged women anthropologists to write about the banking industry, for example, Karen Ho's book, *Liquidated*, and Gillian Tett's riveting account of the 2008 financial crisis, *Fool's Gold*. Melissa Fisher has written *Wall Street Women* and while Sandra Morgen and Mimi Abromowitz have argued that *Taxes Are a Women's Issue* in their 2005 study.

Finally, there has been continued research on gender violence. Sally Merry's *Gender Violence: A Cultural Perspective* (2009) uses personal stories and case studies to provide an overview of the forms of gender violence globally and efforts to diminish it. Hillary Haldane and Jennifer Weiss have headed a group of young women scholars conducting research in a variety of venues across a variety of countries (Wies and Haldane, 2011).

Feminist anthropology is now global. Faye Harrison (2009) outlines some of the differences between African feminisms and those of the West, and describes the impulse to decolonize Western feminisms though forging cooperation and solidarity across cultural, national, and hemispheric lines of difference, a position also supported by Janet Mancini Billson and Carolyn Fleuhr-Lobban (2005). Harrison shows how organizations like the International Union for Anthropological and Ethnographic Sciences can offer spaces for exchanges and collaboration and the building of a broader and more diverse set of feminisms.

Collaboration and Activism

In the second decade of the twenty-first century, many feminist anthropologists feel the feminist movement has faded. Some theorists argue that this is a postfeminist moment. However, there are still protests against rape (the 'slut walks' of 2012), against the narrowing of the right to abortion (protests against defunding of Planned Parenthood in 2012), and struggles concerning access to birth control. Internationally, protests against the treatment of women and girls have been vigorous in India, Egypt, and Afghanistan.

Younger scholars may be reluctant to call themselves 'feminists' but there are many who would identify as queer theorists, those who study women and development, or those who examine gender. Anthropologists have been among the leaders in nongovernmental organizations dedicated to policy-oriented research. Linda Basch, who was director of the National Council for Research on Women between 1996 and 2012, headed an organization that spearheaded research projects on women and girls in science, engineering, and technology; taxes as a woman's issue; retaining women of color in leadership positions; and the importance of publically funded child care. The Institute for Women's Policy Research, where

Jane Henrici, Study Director and President of the Association for Feminist Anthropology (2011–13) is employed, is a public policy 'think tank' that provides rigorous research and public dialogue on the needs of women. A collection edited by Craven and Davis *Feminist Activist Ethnography* (2013) outlines the issues that engage women activists (reproductive rights, food activism, gay marriage, and breast cancer). Feminist anthropologists also describe the organizing strategies their subjects embrace in order to improve women's lives. This form of engaged or public anthropology is increasingly adopted by feminists and is part of a much larger trend within the entire discipline.

Feminist anthropology in the United States has been transformed since its initial expansion in the 1970s. There is no longer a preoccupation with universals or assessing women's status, perhaps mirroring the discipline's move away from grand theories. Instead, there are careful historically contextualized studies that grapple with changes brought by increased globalization and transnational movements of capital and labor. Gender and its intersections with race, class, sexuality, and citizenship provide the lens through which feminists examine and engage with the past and with the issues confronting women both in the United States and across the world. Feminists are more frequently tackling issues that have public policy implications and are more committed to collaborating with and giving voice to individual women, women's movements, and women's issues areas of economy, reproduction, and sexuality. These studies are making an impact in many parts of anthropology including medical anthropology, studies of immigration, urban anthropology, the anthropology of work, and the practice of archaeology. Feminist anthropology is moving in the direction of engendering the discipline.

Abstract

Feminist theorizing and praxis has had a bumpy, yet ultimately successful voyage over several 'waves.' These waves have sought to respond to women's experiences and needs in changing social and political circumstances, eventually recognizing that context matters. Feminism has not only struggled to dismantle patriarchy and transform societies, but it has also responded to the unique cultural contexts in which people live. Today, some argue that we live in a postfeminist age in which feminism is no longer relevant. Others argue that this is a short-sighted view born out of a limited appreciation of the unique cultural contexts on which women's experiences are based, and feminist consciousness is born. This article discusses the multicultural and global trajectories and dimensions of feminisms, paying particular attention to non-Western forms that have received less attention.

Introduction

Women's status, social, economic, and political rights have been defined, defended, established, and then contested. Recent debates about Beyonce Knowles' feminist identity, as well as the assertions by powerful pop icons that they are not feminists have led some to argue that in reality we live in a postfeminist age. During a panel discussion at New York's New School (7 May 2014), feminist author and social activist Bell Hooks expressed qualms about the feminist perspective of Beyonce's projects. Particularly concerned about Beyonce's visual representation and her impact on young women, Hooks noted, "I see a part of Beyonce that is, in fact, anti-feminist, that is assaulting, that is a terrorist ..." (The Hufington Post; http://www.huffingtonpost.com/2014/05/09/beyonce-anti-feminist_n_5295891.html). And in a recent interview with Time magazine actress Shailene Woodley was asked if she considered herself a feminist. Ms. Woodley, 22, answered in the negative, explaining, "Because I love men, and I think the idea of 'raise women to power, take the men away from the power' is never going to work out because you need balance." (The New York Times, 21 May 2014; http://www.nytimes.com/2014/05/22/fashion/who-is-a-feminist-now.html). Others have pointed out that the very fact of a debate underscores the salience of feminist discourse and praxis. Today, it is generally accepted that there is not one but a variety of feminisms, each with unique cultural emphases. However, this contemporary taken-for-grantedness of feminism's multicultural nature did not come without contestations. This article traces the paths to contemporary multicultural feminisms across socio-geo-political contexts.

In 1967, the (Chicago) Women's Liberation Union was formed, birthing the women's liberation movement. In the United States, women's liberation gave way to feminism, a term that has been ascribed to the work of French physician Madeline Pelltier best known for her activism related to women's sexual and reproductive rights and the voting right. However, women had fought for equality before the concept was thus named.

Feminist scholarship enjoys rich and diverse theoretical and methodological traditions (Adomako Ampofo et al., 2004; Essof, 2001; LeGates, 2001; Imam et al., 1997; Mbilinyi, 1992; Mohanty, 1986). This brief review emphasizes the impact of its diverse global, especially Third World adherents. In a piece titled "Sarah Baartman, Invisible!" Adesanmi produces a fictitious letter written by Baartman to Sandra Gilbert and Susan Gubar who produced the Norton Anthology of Literature. Adesanmi (via Baartman) laments the 'excision of African theories and theorists' (2011, p. 109) from this 2452-page 2-volume collection. Sarah Baartman was the most famous of at least two Khoikhoi women who were exhibited as curiosities in nineteenth-century Europe under the now discredited name Hottentot Venus. African feminists have used her story to draw attention to the double burdens of sexism and racism endured by black women. The term feminism is used to refer to the notion of an agenda for women's rights, generally, while feminisms refer to the diverse forms that subsequently emerged in response to cross-cultural differences. The sources for this article include scholarly as well as popular sources published in English, and a Facebook© discussion with black feminist scholars in Germany, the United Kingdom, and the United States. (This is credited to Kara Keeling, Maisha Eggers Peggy Piesche, and Wangui Wa Goro.) The rest of the article maps feminism's global and, hence, multicultural trajectory, tracing feminism's waves and signposting contestations and convergences until the current 'postfeminism' era.

Enculturing Feminism

Elements of feminist theorizing and activism around social justice for women can be found in every modern culture. This section discusses the trajectory of feminism and its 'enculturing.' Feminist theorizing and politics emerged as an organized movement in Western societies in the latter half of the nineteenth century. Histories of Western feminism are often discussed in the context of three waves; each wave focusing on issues influenced by progress in women's rights, and the

inadequacies of an earlier wave. Of particular significance are the contestations between Western and Black/Third World feminists, leading to the formation of diverse feminisms privileging difference.

First-Wave Feminism

Western feminism of the nineteenth and early twentieth centuries has been labeled as first-wave feminism, in relation to the subsequent issues and approaches of the 1960s to 1980s. It emerged in the context of industrialization, the growing organization of the working class in Europe and America, and the so-called liberal politics of the time. This period was principally concerned with equal opportunities for women, and was anchored in a universalist paradigm in which women were undifferentiated. The period was characterized by activism and campaigns – including hunger strikes, picketing, conventions, parades, and marches – for women's education, employment, and legal rights; and for reforms in family life and sexual values. Specific issues included the push for equal pay for equal work, women's rights to vote, and rights to family planning services. This period also confronted female stereotypes and became known as the women's liberation movement. In the United States, women's liberation struggles begun as early as in the 1840s, and were linked with other movements, such as the abolitionist movement. However, the movement was generally by, and for white, educated, middle-class women about their social and political discomforts. For example, socialist feminists constructed marriage and the home as a site of oppression for women, a major point of later disagreement with Third World feminists. Betty Friedan's (1963) 'The Feminine Mystique' for instance, examines the conditions of middle-class American women isolated and excluded from social and productive life. Even so, the nineteenth century struggles were supported by Black women abolitionists, such as Maria Stewart, Frances E.W. Harper, Ida B. Wells, and Sojourner Truth who, with her famous "Ain't I a woman" call agitated for the rights of women of color (Krolokke and Sorensen, 2005). Significant during this wave of feminism was the suffragist movement, which was combined with the struggle to legalize contraception (Antrobus, 2004). Questions of the connections between the institutions of private property, control over assets, and female–male relations within families and society were founded within the social-democratic and communist debates of the late nineteenth and early twentieth centuries, particularly in Eastern Europe. A socialist/Marxist feminism also developed in workers' unions in the United States and social-democratic parties in Europe. Socialist feminism insists on locating feminism within wider movements for economic transformation and social justice. It is this view that paved the way for second-wave feminism.

UN Feminism

A brief detour between the first and second waves to reflect on the role of the United Nations (UN) in the feminist movement is in order here. Technically, UN feminism spans the first and second waves, even stretching beyond the boundaries of second-wave feminism in some cases. The United Nation's role in globalizing feminism, and thus catalyzing multicultural feminisms is undeniable. Meetings held in Mexico City in 1975 marking International Women's Year, and the beginning of the UN Decade on Women, eventually internationalized women's issues. While government representatives of member states attended the official UN meetings, women's groups attended parallel nongovernmental forums. With these NGO meetings began the tradition of measuring states' commitments to, and implementation of, gender equality policies. Follow-up meetings were held in Copenhagen in (1980), Nairobi in (1985), and Beijing in (1995) and women's issues and feminism gained global momentum. This helped women coalesce around common concerns such as discrimination generally, and gender-based violence more specifically. It also highlighted the specific experiences and concerns of women around the world, frequently locating these in discussions of development and underdevelopment, and the complicity of women from the industrialized (Western) world in the exploitation of women in the Third World. Third World feminists objected to underdevelopment being conceptualized as a Third World problem, and this led to a conference and the subsequent well-cited 1991 volume edited by Indian feminist Chandra Mohanty et al. titled, "Third World Women and the Politics of Feminism". Feminist development theorists note that the interaction between feminism and development has taken five main forms: Women in Development (WID); Women and Development (WAD); Gender and Development (GAD); Women, Environment, and Development (WED); and Postmodernism and Development. The WID approach, drawing on modernization theory, advocated for the integration of women into existing development projects and also setting up women-only projects that addressed everyday needs (Kabeer, 1994; Tinker, 1990; Rathgeber, 1990). In many African countries, this agenda was taken over by first ladies and has been described as femocracy (Mensah-Kutin et al., 2000).

The WAD perspective argued that it was precisely women's link with modernization that had impoverished them. Thus, WAD drew much more from dependency and neo-Marxist approaches to questions of underdevelopment. Concerns with the origins of patriarchy, the intensification of patriarchy with the spread of capitalism, and Engel's analysis of the rise of private property and the agricultural revolution formed the background to this approach, which was particularly favored by Third World feminists who supported the social role of the postcolonial state (Kabeer, 1994; Rathgeber, 1990).

In the GAD approach gender (power) relations became the main analytical category. This perspective looked at the structures and processes giving rise to women's disadvantaged position, including the ideology of male superiority. The assumptions in WID and WAD of women as a homogeneous group were critiqued and GAD argued in favor of intersectionality, recognizing that women are differentiated by class, race, religion, and other social characteristics.

The WED perspective was first introduced in the 1975 Mexico-City UN Conference by Vandana Shiva, and was founded on the notion of sustainable development, linking notions of equity between generations, the balance between economic and environmental needs to conserve nonrenewable resources, and the idea of reducing industrial waste and pollution. Sustainable development challenged the notion that development automatically translates into economic growth.

Offshoots of WED are Ecofeminism and, later, feminist political ecology. The late Kenyan Nobel Peace laureate Wanguri Mathai was a proponent of Ecofeminism, and she built the Green Belt movement in Kenya to support women and the environment.

The United Nations and the international discussions it facilitated have shaped the progression of feminist agendas and actions, as well as the recognition that women are not a monolithic category. The United Nations, perhaps through the contestations that erupted during the parallel NGO meetings of the international conferences, and the women's bureaux that were set up in different countries, may also be credited with catalyzing feminism's enculturation. A transparent and collective approach that accepts and understands differences, the power of discourse, and the importance of consultation so that women can articulate their own needs and agendas is favored.

Second-Wave Feminism

Second-wave feminism which began in the early 1960s, and is generally recognized as lasting into the late 1980s, was a response to the perceived lack of politics of the first wave. This wave was influenced by student protests; gay and lesbian movements; the anti-Vietnam war and civil rights and Black power movements in the United States, linking activism with theory-building (Antrobus, 2004; Krolokke and Sorensen, 2005). Theorizations of the subjugation of women were linked to broader critiques of patriarchy, capitalism, imperialism, normative heterosexuality, and women's gender roles; scholars distinguished biological sex from gender.

The second wave is responsible for the concept of 'women's empowerment' that remains influential, and for slogans such as 'sisterhood is powerful' and 'the personal is political,' as well as consciousness-raising efforts (Krolokke and Sorensen, 2005; Ali et al., 2000). The period was linked with, and provided the foundation for, the establishment of formal sites for feminist scholarship around the world – women's gender, and queer units in universities (Krolokke and Sorensen, 2005). The University of Maryland, Baltimore, lists more than 900 women's/gender/feminist study programs, departments, and research centers around the world with web sites. Many more will not have active web sites so this is a very conservative count. While the majority are to be found in the United States, in many places in the global south women's or feminist studies may be subsumed under other programs or within other disciplines and, thus, not be as easy to track via a cursory web search.

Confronted with 'cultural difference' – such as women wearing the (Muslim) veil – many Western feminists perceived themselves as rescuing Third World women from their cultures. This approach exposed tensions between Western and non-Western feminisms. Third World feminists, such as Gayatri Spivak (1988) criticized Western feminists for speaking on behalf of Third World women. Some, like Mohanty (1986), even opined that the glossing over of the diverse experiences, cultures, and histories among Third World women was a political project to subjugate Third World women. They further criticized Western feminists for speaking naively on behalf of Third World women. Thus, a fundamental shift in second wave feminism was the insistence on the importance of differences among women. Questions of the body, sexuality, female genital mutilation, the family, and motherhood emerged as key points of contention between Western and non-Western feminists. Radical Western feminists argued that women (should) have rights over their bodies, advocating a sexuality disconnected from the obligations of marriage and motherhood. Third World feminists disagreed and nowhere did this present itself more sharply than during the International Conference on Population and Development, ICPD held in Cairo in 1990 where many African representatives insisted, without apology, that abortion was not a key concern, and that motherhood remained central to their identities especially as it linked them to, or provided respite from, lineages as the case might be. Motherhood also provided status, and emotional and economic support. Third World feminists also insisted that the (over) emphasis on sexuality was misplaced and that they had the right to privilege their own concerns. African women in particular were very unhappy with a focus on female genital mutilation to the near-exclusion of other issues and without any attempt to understand the cultures in which the practice was located. The delicate home of global sisterhood based on a notion that feminism could create an alliance based on the commonality of womanhood and the patriarchal societies they lived in crumbled. At one meeting organized by the Nigerian feminist Nnaemeka Obioma in Nsukka in as late as 1992, African Americans and some African participants even objected to the participation of white women. The factions that emerged necessitated a questioning of the comfortable notion of global sisterhood (Nnaemeka, 1998). It saw the beginning of 'standpoint feminism' (Chodorow, 1978) and identity politics. Women of color, working-class, Third World, and lesbian feminists questioned the predominantly White, middle-class, and heterosexual feminist agenda of liberal, socialist, and radical feminists, accusing them of "ignoring, trivializing, or distorting the lives of women who were 'different' through other forms of othering" (Friedman, 1995, p. 9). The concept woman could no longer "bear the weight of all contents and meanings ascribed to it" (Gillis et al., 2004, p. 1). These accusations caused essential reconceptualizations in the feminist theory.

Third-Wave Feminism

Third-wave feminism emerged in the mid-1990s, the period of many of the UN World Conferences on Women and the signing of international agreements such as the Convention on the Elimination of all Forms of Discrimination against Women (CEDAW). These meetings meant that feminists from all over the world had begun to interact. It was also the beginning of an ICT society, meaning women could now meet virtually as well. Third-wave feminism finally addressed difference, speaks of feminisms, and makes room for contradictions. Terms such as the body, gender, sexuality, and 'heteronormativity' were deconstructed. This wave concerned itself with interrelated issues including environmentalism; human rights; domestic violence; women in politics; eating disorders, body image, and reconstruction; hegemonic knowledge production; globalization; and the effects of racism and classism. Third-wave feminists advocate self-location and positionality and an

antihegemonic global feminism. An important contribution to Third-wave feminist thinking is the notion of 'transversal politics' launched by Yuval-Davis (1997), a British Jew. Inspired by Spivak's theory of 'strategic essentialism' and Collins's theory of the 'partiality of standpoints' and 'situated knowledge' Yuval-Davis presents possibilities of dialogue between women across national, ethnic, and religious boundaries. Yuval-Davis was also inspired by the politics of feminist activist groups such as the London-based Women Against Fundamentalism (WAF) – which includes Christians, Jews, Muslims, Sikhs, Hindus – and others such as the Bologna feminists, who work with women from groups in conflict, such as Serbs and Croats or Palestinian and Israeli Jewish women who work across typical identity schisms. Transversal politics recognizes differences in nationality, ethnicity, or religion – and hence in agenda – but also requires a commitment to listen and participate in dialogue.

Black and Third World Feminisms

The distinguishing lines are very blurred, however, Black feminism typically focuses on the Diaspora experience. North American Black Feminism has its roots in nineteenth century abolition movements articulating Black resistance and advocacy for social, political, and economic equality (Krolokke and Sorensen, 2005). It is laden with accusations of racism in white feminism that ignores the particular histories of slavery, and neglects the racial oppression and invisibility of women of color and Black feminists (Collins, 1990). White feminists' concerns for the right to abortion, for instance, ignored the subject of the forced sterilization of Black women. Influential texts include Barbara Smith's "Toward a Black Feminist Criticism" (1977), Alice Walker's "In Search of Our Mothers' Gardens" (1983), Bell Hooks' "Ain't I A Woman? Black Woman and Feminism" (1981), Hazel Carby's "White Woman Listen!: Black Feminism and the Boundaries of Sisterhood" (1982), and Audre Lorde's "Sister Outsider" (1984). Black feminists argued that their political reality was one of a simultaneity of oppression, underscoring the notion of interlocking identities or intersectionality. Indeed, in her landmark text "Black Feminist Thought," Collins (1990) insists that in order to appropriately examine and respond to black women's lives, (black) feminist theory must be built simultaneously on the experiences and effects of race, gender, and class. Crenshaw (1989) coined the term 'intersectionality' to describe how 'multiple oppressions' are experienced, and Collins (1990) introduced 'the matrix of domination' to analyze how these intersecting oppressions are actually organized. Black feminists formed organizations to fight these multiple oppressions including the National Black Feminist Organization (NBFO) of 1973 and the Boston-based Black lesbian feminist Combahee River Collective of 1974. The Collective also expanded the by-now popular feminist mantra, "the personal is political," to include the notion that the personal is also cultural. They note that "Even our Black women's style of talking, testifying in Black language about what we have experienced, has a resonance that is both cultural and political" (Combahee River Collective, 1982, p. 17). Further, unlike white lesbian feminist separatism, the Collective advocated an inclusive political strategy that would enable black women and men to fight together against racism while simultaneously challenging sexism. Indeed, Black feminists have sought to differentiate their feminisms via naming, to include the traditions and values within black communities. Some reject the term feminism altogether preferring to discuss issues of gender. The unease with the term feminist goes beyond culture as Purkayastha et al. note: "unease arises from how the conceptualization of individuals is taken for granted. A sharp distinction is assumed to separate the individual from any collectivity" (2003, p. 506). Along comes 'womanism' a key feature of which is the need for community – including men – to fight injustice, and not merely an emphasis on individual advancement or emancipation. Alice Walker is credited with introducing the term 'womanist' in 1980. The term was adopted by many African feminists independently of Walker (see Ogunyemi, 1985). 'Womanism' is equated to Black feminism, and is portrayed as superior to White feminism – promoting relations between women and men; privileging motherhood, community, and spirituality. A fourth definition, according to Walker, and where she deviates from African womanism, speaks of romantic love between women, thereby making a claim for Black lesbian feminism. African women outside of Southern Africa have generally not embraced the LGBT movement, even though same-sex love between women, including romantic love, is increasingly acknowledged and discussed (see Tamale, 2011). Audre Lorde, lesbian feminist activist, was instrumental in linking heterosexuality with discussions of women's oppression. She used her writings and speeches to argue that heterosexuality is institutionalized to perpetuate the social power of men across class and race. In Germany, Eggers referenced a series, 'Adefra,' with Peggy Piesche and Katja Kinder where they talk about The Black Women's Movement in Germany. On the level of practice, Black Germans, through 'Adefra,' have also always found it important to "share activist spaces with brothers, sometimes children and grown children of Black women Activists, sometimes siblings, sometimes fellow activist comrades from other organizations" (Maisha Eggers, personal communication on Facebook, 2 March 2014). This leads to conflicts with the White Women's Movement in Germany who had a strict no-men policy. '"Adefra' is also a space that embraces Black Lesbians. In the United Kingdom also there are fractures born of race and class differences – white women do not generally accept class issues based on race, while some black women do not find issues of sexuality a priority. In the Facebook© discussion, Wa Goro points to the longest surviving organization, the Southhall Black Sisters set up in 1979 to meet the needs of black (Asian and African-Caribbean) and minority ethnic women (http://www.southallblacksisters.org.uk/). Although the term womanist has declined in usage, the term did enjoy a brief renaissance with the publication of the Womanist Reader (Phillips, 2006). Although black women insisted on their special circumstances, African and African-American feminists also built effective relationships with White feminists on specific issues such as access to services including day care, reproductive health care, maternity leave, and prevention of and support for domestic/gender-based violence. This was admitted during the first conference of the National Black Feminist Organization in 1973.

Third World Feminisms

The Third World has been defined severally (Spivak, 1988; Sangari, 1990). Third World women have diverse experiences with different local, national, and regional contexts. However, the commonality of the shared experiences of slavery, colonization, imperialism, and capitalism unifies them in unique ways (Spivak, 2006). Third World feminisms have been heavily influenced by globalization, international funding for national NGOs, transnational advocacy groups, and the UN organizations. These further expose, influence, and increase the tensions that exist between feminisms. Early encounters between feminists from different countries during the nongovernmental forums of the UN women conferences resulted in claims that Third World women were not feminists – or feminist enough – as they did not prioritize the issues that Western feminists considered critical. In *Under Western Eyes*, Mohanty et al. (1991) contest the Eurocentric gaze that privileges Western notions of progress and arbitrarily homogenizes Black women as victims of ignorance and restrictive cultures (Mohanty, Spivak (1988)). Other Third World scholars contest Western feminism's naivety in speaking on behalf of Third World women, and about non-Western social structures they do not understand (Oyewumi, 1997).

Today, the categories that would be considered Third World are numerous and fluid – Asian, Arab, African, Caribbean, Latina, Indigenous peoples, etc. The problematics around the terms, for example, 'Asian women' has been discussed at length by scholars such as Arisaka (2000). At best, it is an ambiguous category, at worst, laden with racial (racist undertones such as non-Christian (i.e., heathen or barbaric)). There are many influential texts reflecting the diverse Third World experiences, approaches, and theories. However, one could summarize the following as critical areas that have received much attention: women's visibility and voice in politics; violence against women; sexualities; and relations with the state. Useful reviews/accounts include those by Bayoumi and Sidawi (2014) and Saadawi (2007) on the Arab world; Loomba and Lukose (2012) on South Asia; Purkayastha et al. (2003) and Maitrayee (2005) on India; and Mihesuah (2003) and Pettman (1992) on Native Americans and Australian women, respectively.

African Feminism

The origins of African feminism(s) cannot be specifically dated, and we distinguish this from Black feminism to underscore a more conscious link to the continent. It can be argued that it predates colonialism certainly in purpose if not in name as one is dealing with several languages that predate the introduction of European languages in the continent. This is evidenced by women's specific struggles for their gender concerns. African feminism has been defined as an intellectual and activist movement, rooted in the experiences of slavery, colonialism, and patriarchy and striving to end interlocking systems of multiple oppressions resulting from these experiences and their conditions (Adomako Ampofo and Arnfred, 2009; Adomako Ampofo et al., 2004; Mama, 2011; Steady, 1981). Significant attention is paid to describing precolonial and traditional systems of gender relations to help understand connections to contemporary experiences, thus it is very much grounded in relating lived experiences to theorizing, and addressing issues such as health, gender-based violence, sexuality(ies), education, the family, work, politics, the state, and women's organizing (Adomako Ampofo et al., 2004). This important criterion for scientific enquiry has often led to the unfortunate accusation that African (scientists) feminists are mere empiricists. It is recognized as heterogeneous, bearing the marks of its multiple and diverse colonial contexts, and influenced by a multiplicity of civilizations (Islamic, Christian, and indigenous) before being further shaped by an array of anticolonial, anti-imperialist and nationalist movements, and interactions with (white) Western feminism (Norwood, 2013; Mama, 2011). African feminisms have been "fundamentally deconstructive, inherently rebellious and unapologetically anti-imperialist, antiracist, antisexist, and (recently, since the third wave) antihomophobic" (Norwood, 2013, p. 226). They also have problematized White Western feminism(s) and the production of knowledge on Africa, introducing alternative concepts, methodologies, and theorizations that valorize African-centered knowledge. Particularly significant have been the scholar-activist collaborations that have addressed the social and political concerns of women and that have been instrumental in women mobilizing. Adomako Ampofo (2009) maps some of the significant moments in these collaborations, significant among them the setting up of the electronic network, GWS, at the then African Gender Institute at UCT, and the subsequent establishment of the flagship e-journal, *Feminist Africa*. The journal's subject matter reflects the diversity of issues of concern as well as its activist edge. Along with other units, the African Gender Institute has since been merged into a School for African & Gender Studies, Anthropology & Linguistics (see more at: http://www.humanities.uct.ac.za/hum/departments/axl#sthash.A6ZNgE2b.dpuf). A recent issue of *Feminist Africa* (2006, p. 7) has been devoted to Diaspora voices in which Reddock, a well-known Caribbean feminist scholar wrote the Editorial, and Barriteau, Rajack-Talley, Safa and Boyce Davies, fellow Caribbean feminists are contributors. In addition to defining, problematizing, and celebrating *diaspora* (Reddock), the contributors provide an eloquent summary of the status of black feminism for women in the Caribbean and in Brazil. As with continental Africa, much of the literature engages with the state's neglect of women's concerns, or their direct complicity in women's oppression. Additionally, Caribbean feminists have been concerned with issues of identity (e.g., Mohammed, 1998) and masculinities. Nnaemeka (1998) and Reddock (2006) provide excellent summaries of some of the better-known conferences and anthologies that have taken place about African women's issues, particularly in Africa, and that have provided opportunities for important collaborations.

Post–Third-Wave Feminisms

This period is so named to reflect emerging issues and the technological tools of the new millennium, as well as the post-9/11 culture-of-war. There are increasing engagements with states and international organizations in discussions around citizenship, identities, globalization, peace and security, terrorism, climate change, and food security; and feminists have recognized the need to coalesce around these. This wave

includes intergenerational feminisms, and the use of social media in feminist engagements. As part of Facebook© discussions with Black feminists in Europe, Maisha Eggers, in Germany, paid tribute to the power of digital campaigns for black women's spaces in Europe. She offered the example of a campaign, "My feminism will be intersectional, or it will be bullshit."

The narratives and methods of a younger generation's experiences have introduced new issues and approaches. We find a feminism that manifests itself in 'grrl' rhetoric, which challenges the notion of 'universal womanhood' and embraces ambiguity. Younger feminists of this era adopt body expressions of femininity that earlier feminists identified with a male oppressive culture (Baumgardner and Richards, 2000; Gillis et al., 2004). The attitude is that, "it's possible to have a push-up bra and a brain at the same time" (Pinkfloor cited in Krolokke and Sorensen, 2005, p. 20). Popular culture is engaged with, while sexist language and inappropriate terms such as 'slut' and 'bitch' are criticized. Discussions on feminism and popular culture are linked with cultural studies and gender roles, exploring the ways in which feminism and popular culture influence each other. The interactions have revealed the sexist representations of women that societies consume and take for granted. Of particular importance has been the objectification of women in audiovisual media and advertising. Munford and Waters point out that popular culture celebrates models of privileged 'housewifery' that encourage 'fairy-tale idealizations of feminine idleness' which is a concern in feminist discourses (2013, p. 93). Significant in this 'post-era' are discourses around religion and fundamentalism, Euro-American attitudes toward Islam particularly, and the resistances to these attitudes that have fed feminist theorizing and activism about the place of Muslim 'others' in Europe. Rottmann and Ferree (2008) compare feminist discourses around Europe's antidiscrimination legislation and headscarf cases in Germany, showing that the relationships among race, religion, gender, and the role of the state influences German feminists' discussions, particularly feminists of color. Traditionally, Islamic women who wear the veils or headscarf have been viewed as not 'feminist enough' or worse, as culturally backward (Mernissi, 1987). Ignored is the role of the veil to protect, or even empower women in contexts where their movement is otherwise circumscribed or even limited, or worse, where they are exposed to sexual harassment (Odeh, 1993). The discourse addresses the confrontations among globalization, terrorism, feminism, and war. In their edited volume, *Feminism and War: Confronting US Imperialism*, Riley et al. note the annihilating effects of war on the lives of women and how women's liberation is invoked "to justify, legitimize and continue wars through the use of racialized discourses of male supremacy and female helplessness" (2008, p. 11).

This 'post-era' also enjoys convergences. The issue of motherhood, for instance, has now gained such prominence in North America that an entire series is dedicated to it by Demeter Press. Convergences do not lead to a (re)universalization of womanness, however. Rather, global feminisms are approached in terms of similarities and differences, and exchanges of ideologies, human resources, political movements, and transnational feminist collaborations and activisms (Lal et al., 2010). One such successful collaborative project is the Pathways of Women's Empowerment project coordinated through the Institute for Development Studies, IDS, Sussex, and with partners in four regional hubs – South Asia, Latin America, North Africa, and West Africa.

Challenges remain, however. Finding a nuanced position that can specify women's particular social locations, their universal human rights, and a feminist identity is not easy. As Mohanty (1986) noted, a focus on universal gender oppression can mean that particulars such as race and class must become invisible in order for gender to become visible. Valorizing differences – sexualities, religion, global location, class, generation– while keeping the larger project intact requires deep sensitivity and skillful balancing.

There are also backlashes. Wa Goro notes, "As with 'Black' advancement, these [feminist] issues seem to take on cyclical and 'one step forward two steps back' kind of patterns. These are also differentiated in various contexts at any time, with some progressive pockets in some arenas with simultaneous backlashes or backsliding elsewhere as in all struggles... and of course the mass media have a role to play in deciding whether to advance these ideas or not, based on the wider political/economic reality..." (personal communication on Facebook discussion, 3 February 2014). As long as gender-based inequalities remain we will need feminism. But for feminism to survive it must be inclusive. In the words of Bryson, "what we dare insist on for the survival of feminism is that we share this movement towards an open-minded, generous, and inclusive feminism that moves beyond modern/postmodern, local/global, theory/practice and academic/real world dichotomies in what some might describe as a dialectical resolution that builds upon the best of earlier thought and experience to suggest ways forward for the future. Rather than suggesting that feminism is moribund, they show the breadth and diversity of feminist politics and ideas, the ability to develop even in a hostile climate, and the continuing importance of feminist concerns." (Bryson, 2002, p. 239).

Feminist Criminology and Gender Studies

Susan F Sharp, University of Oklahoma, Norman, OK, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Feminist criminology refers to approaches to the study of crime, victimization, and the criminal justice system using a critical, feminist lens. There are many different theoretical approaches, including standpoint feminism, pathways theory, and engendering mainstream theories. These approaches have a critical analysis of how gender inequities shape crime and responses to crime, emphasizing the role of male hegemony in society. Feminist criminology began in the 1970s, with liberal feminist approaches, followed by examination of the roles of victimization and abuse in female offending. These early feminist works were informed by second-wave feminism. More recently, third-wave feminism has informed multicultural and postmodern approaches in feminist criminology. Feminist criminology may use quantitative, qualitative, or mixed methods approaches. The subject matter includes women as victims, women as offenders, women working in the criminal justice system, and masculinities and crime.

In the field of gender studies, criminology has remained more androcentric (male centered) than most social sciences (Britton, 2000), in part because men commit both more crimes and more serious crimes than women commit (Flavin, 2001; Steffensmeier and Allan, 1996). Criminology focused for decades on crime by males and theories derived from the study of males, largely ignoring women. Most theories of crime that were developed prior to the 1970s were based solely on research with males, and their applicability to females was ignored (Heidensohn, 1969). Criminology was criticized mid-twentieth century by feminists for ignoring gender, where men were seen as the norm. Thus, feminist criminology is a relatively new approach to the study of victimization, criminal offending, and the criminal justice system. Feminist criminology is not simply the study of crime by women, nor is it just the study of women and crime. There are males who are feminist criminologists, and there are many female criminologists who are not. Additionally, there are many examinations of women and crime that are not feminist. Feminist criminology explicitly takes into account the unequal power of males and females in its approach to the study of crime and justice.

Overview of Feminism in Criminology

Feminist criminology might be more aptly named feminist 'criminologies,' feminist perspectives in criminology, or feminist epistemologies of crime. The field comprises diverse approaches and theories. What these have in common is the focus on gender as central to criminological inquiry. Feminist criminology is not a specific theory but rather application of feminist perspectives to the field of criminology, with multidisciplinary roots and perspectives. One of the hallmarks of feminist criminology is that it is grounded in the examination of gender relations in society. As in any feminist theorizing, the central focus of feminist criminology is the understanding of how gender informs the understanding of social actions, in this case criminal behavior and victimization. The integration of feminist thought into a primarily male-oriented discipline has resulted in a range of loosely related theories and approaches.

Feminist criminologists have also criticized mainstream criminology for the gendered reproduction of knowledge that keeps criminology focused on the experiences of men (Renzetti, 1993). The problem is that feminist perspectives are usually separated from other theories in textbooks and given only cursory coverage. They also are rarely published in mainstream journals. Thus, generations after generations of students are unaware of feminist criminology and its contributions. They in turn teach their own students mainstream theories, with little, if any, reflection on more explicitly feminist approaches. Although it is becoming more mainstream today, feminist work is still largely relegated to specialty journals such as *Violence against Women*, *Women and Criminal Justice*, and *Feminist Criminology*, in special issues of other journals, or in trade books and texts on feminist criminology. This leads to a reproduction of knowledge that largely overlooks feminist thought. However, some mainstream theorists such as Agnew (Broidy and Agnew, 1998) have pointed out the importance of incorporating feminist approaches, not just women, into criminology as a field of study.

Feminist Criminological Approaches and Methodologies

Drawing from feminist theories in general, feminist criminologists tend to fall into three broad camps. Liberal feminist and radical feminist approaches undergirded much of the first two decades of theorizing and research in feminist criminology, while postmodern approaches have gained prominence in the last two decades.

In liberal feminism, the focus is on obtaining equality in the public sphere. This has led to efforts to achieve gender parity in prison educational and therapeutic programming. While this is beneficial, women prisoners' needs do not mirror those of men. Simply adding the same or similar programming and services

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45059-2

may fail to address women's health and mental health needs, which differ significantly from those of men. Thus, an explicitly feminist approach is needed to determine the needs of women prisoners. There is a dark side to liberal feminist efforts, with parity being translated as applying equally punitive approaches to women's corrections.

In contrast, the work of radical feminists has largely focused on women as victims. Radical feminists have largely focused on how societal inequality and patriarchy lead to gendered violence. Another important aspect of radical feminist criminology is the focus on activism to bring about social change. Radical feminists have worked to address reproductive justice and the criminalization of women's bodies, as well as on violence against women.

As a part of third-wave feminism, a third approach has gained prominence in feminist criminology over the last two decades. Postmodern feminism focuses on the intersections of gender, class, and race, arguing that there is not one overarching experience for women. Instead, an individual is placed in a variety of social positions. The impact of each of these (race, class, sex, nationality, age, and sexual orientation) is not simply additive. Instead, oppression is often multifaceted. To accurately describe and report the experiences of women as victims or offenders, it is important to understand these interlocking systems of oppression.

Within the broader approaches of second- and third-wave feminism, there are feminist empiricists and standpoint feminists (Ngaire, 1996). Feminist empiricists adhere to mainstream scientific methods, incorporating women and their viewpoints in the analyses. Feminist empiricism has helped broaden the knowledge about crime and the criminal justice system overall by incorporating the perspectives of women into research (Flavin, 2001). Empirical feminist work strives to measure some agreed upon reality in the social world (Daly, 1988), and may or may not be feminist. Standpoint feminists go further, challenging the validity of knowledge from empiricism. The standpoint perspective argues that knowledge is shaped by the power relations in society and thus never completely objective. They begin with the standpoint or position of the individuals under study (Daly, 2008; Flavin, 2001). Both are considered feminist approaches. Finally, some feminists take a deconstruction approach to challenge either–or binary thinking patterns about gender and other social placements, focusing instead upon the complex nature of social location (Daly, 2008).

There is also no single methodological approach that is considered to be feminist, either. Feminists may do quantitative analyses or qualitative work. However, simply adding gender as a control variable does not make the work feminist. Instead, careful research designs are utilized based on theoretical perspectives that take into account the hierarchical gender structure of society. In-depth interviews and life histories are types of qualitative approaches, with an emphasis on depth and meaning rather than description. Qualitative work focuses far more on meaning and process. Daly (2008) suggests that using both qualitative and quantitative approaches is desirable in the development of theory.

Reflexivity is a final important aspect of feminist research. It is intricately linked to both theory and method. Reflexive work critically analyzes the underlying assumptions involved in the work as well as the process. Feminist criminologists consider this an important part of doing research, because the goal is to identify bias introduced into the process. For some feminist researchers, reflexivity may include examining their own reactions to the research (Flavin, 2001). Additionally, feminist researchers are aware of the imbalance between the researcher and subject. In particular, feminism cautions against the potential for exploitation (Flavin, 2001).

It is readily apparent that theories and methods vary widely among those who consider themselves to be feminist criminologists. Additionally, the degree of reflexivity can range from identifying potential biases to reflection on the researcher's role in the process. Feminist criminology, however, has added to the knowledge about why both women and men commit crime, as well as the roles of personal history and social placement. It has drawn attention to inequities in the system, and usually called for change. Activism and praxis are both parts of feminist approaches to criminology, which sometimes put feminist criminology in conflict with a more mainstream approach that assumes research should be objective and detached.

Development of Feminist Perspectives in Criminology

While there were a few studies of female crime in the past, the role of hierarchical gender relations was largely ignored. The focus was on women offenders as women who deviated from socially accepted gender roles. For example, Lombroso and Ferrero (1893, translation by Rafter, 2004) tried to explain women's crime by suggesting that women who committed crime were more like men than like other women. Their argument linked women's sexual behavior with criminality, suggesting that women who were more sexually aggressive were more masculine. They believed this masculinity led to female offending. Likewise, in *The Unadjusted Girl*, Thomas (1923) focused on female sexuality and equated promiscuity with delinquency. Little if any attention was paid to the relative powerlessness of women or how patriarchal society controlled their sexuality and work. In a more negative analysis, Pollak (1950) argued that women were more devious than men, and their crimes were more hidden. Thus, their underrepresentation in the criminal justice system was due to their cunning as well as chivalrous and preferential treatment, not lower levels of offending. Recent research, however, has underscored the reality that females offend less often and less seriously than men. Feminist criminologists point out that understanding women's offending and their lower offending rates can aid in understanding male offending.

During the second wave of feminism, two books on women and crime were published that illustrate the difference between the study of women and crime and what is more generally considered to be feminist criminology. Adler (1975) published *Sisters in Crime*, arguing that as women gained more opportunities in mainstream society, this would translate to masculinization of women and more crime. She envisioned higher levels of property crimes by women as a result of their 'liberation.' Similarly, Simon (1975) argued that women's 'emancipation' would create more opportunities for women. The response of feminists to these two approaches was that neither considered the role of a patriarchal society in which

males exercised control over women's sexuality as well as their workforce participation. Furthermore, this approach was based on the faulty assumption that women had achieved equality. Thus, the contributions of Adler and Simon are generally not considered to be part of the body of feminist criminology, although some consider their work to exemplify liberal feminism due to the focus on legal and economic equality (Daly and Chesney-Lind, 1988). At the same time, second-wave feminism gave birth to a growing awareness of the importance of placing women at the center of the study of crime. This led to further work that was more overtly feminist.

Although there were important contributions prior to the publication of Carol Smart's (1976) critique of mainstream criminology, the emergence of feminist criminology is often attributed to her book. Her work was the first explicitly feminist approach to the study of women and crime and critique of mainstream criminology. Following its publication, a body of research and theory began emerging that is considered to be feminist criminology.

In an important treatise on feminist criminology, Daly and Chesney-Lind (1988) point out that there are two important issues that should be addressed by criminological theory. First, theories should be able to address the gender gap or gender ratio issue. In other words, since males commit more crime and more serious crime, theories should help us understand why this occurs. This requires careful consideration of gender roles and gendered imbalances in power that help predict the higher rates of male offending and lower rates of female offending. Second, criminology needs to address the generalizability issue. It should be able to explain not only men's, but also women's offending. Daly and Chesney-Lind (1988) further delineate five elements of feminist thought that must be taken into account for a theoretical approach to be considered truly feminist. First, it must take into account that gender is a complex set of cultural and social aspects that are related to biological sex differences. Second, feminist thought is based on the understanding of the ways that gender organizes social life and social relations. Third, this organization of social life and relationships is hierarchical. Males have more power than females. Fourth, this male hegemony results in the systems of knowledge reflecting the male view of the world. Thus, scholarship and knowledge maintains a strong gendered aspect. Finally, feminism argues that women should be at the center of intellectual inquiry (Daly and Chesney-Lind, 1988).

Much of early feminist work focused on the overt control of women's sexuality, the misrepresentation of female offenders in mainstream criminology, and the dearth of scholarship that focused on the role of patriarchal society in female offending. During the 1970s and early 1980s, considerable work began emerging that argued that it was the explicit control of girls' and women's lives that resulted in their criminal justice involvement. In particular, Chesney-Lind and others began delineating the gender inequities in the juvenile justice system. Chesney-Lind focused on the overdetention of minor girls for status offenses and how that was related to efforts to control young girls' sexuality. Furthermore, girls often engaged in status offenses because of abuse, especially sexual abuse in their homes. She found that girls were far more likely than boys to be detained for offenses like running away and curfew violations. In contrast, boys were more likely to be detained for criminal offenses and rarely entered into the system for status offenses. Taking an overtly feminist stance, Chesney-Lind (1973 and other work) argued that these status offenses were often due to girls' responses to abuse in the home. Girls who were abused protected themselves by running away from the abusive environment and consequently found themselves caught up in the juvenile justice system and labeled delinquent.

During the 1970s and 1980s, feminist criminological work tended to focus on three main areas: women as victims, women and girls as offenders, and institutional reactions to women's and girls' offending. At the forefront of the emerging body of feminist criminology, important work on intimate partner and sexual violence began appearing. This work was largely an outgrowth of the second wave of feminism. The decidedly masculine nature of both physical and sexual violence and the fact that victims of intimate violence and sexual violence were overwhelmingly female underscored much of the work during the late 1970s and 1980s. Susan Brownmiller's (1975) classic study of rape brought attention to the power dimension of rape, redefining the crime as one of male dominance. Feminist criminologists brought a variety of perspectives to bear on male victimizers, female victims, and the ways in which the gendered social structure facilitated violence against women. Indeed, so much research was published in this area and feminists took such a strong activist stance that the Violence Against Women Act was first passed in 1994, with reauthorization in 2000, 2005, and 2013. In 1995, the academic journal *Violence against Women* was launched, focusing on primarily feminist research in this area. One of the contentions of feminist criminologists who focused on violence against women was that women's victimization was qualitatively different from men's victimization because of their lesser power and the high probability that the perpetrators were related to the women through familial or romantic liaisons. Activism by radical feminists was successful in achieving redesign of the National Crime Victimization survey to specifically ask about sexual victimization and victimization by family members and intimates. This has added considerably to the knowledge about violent and sexual victimization.

Feminist work has also focused on domestic or intimate partner violence. In reaction to research suggesting that women were as abusive toward romantic partners as males, feminist work has focused on the power differentials between men and women and on women as victims. Early work (Dobash and Dobash, 1979) focused more narrowly on the abuse of wives by husbands. More recent feminist thought argues this is too narrow, adopting the term 'intimate partner abuse,' which includes physical, sexual, and psychological abuse, as well as destruction of pets and property (Tong, 1984). Feminists have also sought to dispute research that suggests that women are as violent toward their partners as men. Much of that body of work uses the Conflict Tactics Scale developed by Straus and Gelles. Feminists take issue with two aspects of that instrument. First, it fails to take actions in context. Because it is a simple count of actions taken by the subject and the subject's partner, it is impossible to determine the context. The question of whether the counted action was in reaction to force from the partner is unanswered. More importantly, mere counts of aggressive behaviors do not

capture the level of seriousness and the harm caused by the action. Feminists argue that the data show that abuse of females by males leads to more serious harms.

By the middle of the 1980s, feminist criminologists were developing theories to explain female offending as well as examining the experiences of women caught up in the criminal justice system. Early works by Carlen (1983) and others sought to provide a more accurate portrayal of who women who offended were and how their life histories explained their offending. By the 1990s, there were numerous books available on women and offending, many from a feminist perspective. The role of childhood maltreatment began emerging as a major explanatory factor in the offending of girls and women (Acoca, 1997; Chesney-Lind, 1973). Research began focusing on the early lives of female offenders, noting the high prevalence of sexual, physical, and psychological abuse as well as neglect. Feminist pathways approaches have focused on the lives of women prior to their offending, attempting to address the reasons why women and girls offend. Early pathways research utilized interviews with prostitutes, while more recent work has used incarcerated women and girls to further develop the understanding of female offending. An important aspect of pathways approaches is the use of the voices of the girls and women themselves. Pathways approaches have documented the link between victimization and offending (cf Acoca, 1998; Belknap, 2007). Abuse in both childhood and adulthood has emerged as a common theme. Women who were abused as children enter abusive relationships in adulthood. Mental health problems often occurred, and substance abuse was frequent (Owen, 1998).

During the same time frame, work began emerging that focused on women's experiences in the criminal justice system. In one of the most thorough treatments, Owen (1998) provides an in-depth examination of the experiences of women in prison. Others have focused on questions about unequal treatment in crime processing. Still others have utilized the knowledge gained about the backgrounds of female offenders to challenge to programming available to women and girls in the criminal and juvenile justice systems. Because of the intricate relationship between women's victimization and their offending, gender-sensitive and trauma-informed programming has been introduced into various systems around the world.

The next important development in feminist criminology was recognition of the differences among women rather than focusing on gender as a unilateral trait. This postmodern approach has emphasized that race, ethnicity, class, national origin, religion, immigrant status, and sexual orientation play both independent and interlocking roles in the lives of women (cf Richie, 1996). Informed by emerging critical race feminism in other fields, feminist criminology began incorporating a multifaceted lens that took into account the multiple social placements of women. Potter's (2006) Black Feminist Criminology focuses on the unique experience of African-American women, while Burgess-Proctor (2006) focused on the need for an approach that examines multiple systems of power and oppression.

Feminist criminology focuses in part on the gender gap in offending, examining the role of gender in the occurrence of crime. As described above, criminology should not only describe why women offend less but also why men offend more. Thus, it has also contributed to studies of masculinity and crime. Messerschmidt (1993) has produced a body of work on masculinities and crime that is considered to be feminist. His work focuses on three elements of the social structure that increase the likelihood of male offending: the gendered division of labor, male hegemony, and sexuality. His approach takes into account not only gender but also social placement, especially sexuality, race, and social class. Because the patriarchal social structure expects men to be more successful, this becomes the goal of young men. Those males born into a more privileged class (middle), race (White), and who exhibit the preferred sexual orientation (heterosexual) have access legitimately to success, through education and occupation. For those who are not as fortunate, nonlegitimate avenues of success, such as crime and delinquency, are used to establish success. From Messerschmidt's perspective, masculinity is what best explains the commission of crimes, because males feel pressure to demonstrate power. In general, women do not have this issue, so they offend at lower rates and for different reasons. While Messerschmidt has taken a feminist approach to explaining male criminality, his work does not provide an explanation for why females commit crime; thus, it addresses the gender ratio issue but not the generalizability issue raised by Daly and Chesney-Lind (1988).

It is also worth noting that some feminist criminologists focus on gender and work in the criminal justice field. Because of the masculine nature of crime and male hegemony, very few women worked in most areas of the criminal justice system until the late 1970s and early 1980s (Belknap, 2007). The blockage of women from opportunities has been blamed at times on the lesser physical strength of females. This presupposes that women are incapable of performing as police officers or working in prisons. Despite Title VII of the Civil Rights Act, women can still be legally barred from occupations through application of bona fide occupational qualifications (Belknap, 2007). These can be used to argue that a man should be hired for the position because it is more rational to do so. Thus, even in the twenty-first century, women remain grossly underrepresented in both policing and corrections, although their representation is higher.

Working in prisons can often be difficult for women, particularly if they are oriented toward helping. Belknap (2007) takes the stance that one should not use the term correctional officers because of the paucity of rehabilitation in the prisons and jails as well as the lack of rehabilitative training by prison and jail workers. Additionally, women may face difficulties with promotion opportunities. One line of thinking suggests that women should be employed in women's prisons because the prisoners have been traumatized by males and will respond better to females. The problem is that there are far fewer women's prisons and therefore fewer chances for advancement. When women are relegated primarily to women's facilities, they often find themselves unable to advance in their careers, while similarly placed males in men's facilities are promoted (Baunach and Rafter, 1982). Another argument is that it is

a violation of privacy for women to work in men's facilities (Belknap, 2007).

Women have been in the field of policing longer, but they have also faced numerous restrictions there. Initially, they worked as matrons, and during the first decades of the twentieth century they often were confined to specialized roles in line with tradition gender roles. Their positions were often with youth or women and were primarily custodial (Belknap, 2007). As late as 2005, only approximately 10% of police officers were female (Belknap, 2007). Reasons include perceptions that women are less capable, incompatibility of shift work with raising families, physical limitations, and resistance by male officers' (Natarajan, 2001) requirements.

Feminist Criminology and Professional Organizations

The two major academic organizations in criminology, the American Society of Criminology (ASC) and the Academy of Criminal Justice Sciences (ACJS), both have subdivisions that are profeminist. The Division on Women and Crime (DWC) of the ASC grew out of an informal group that emerged into a caucus in the larger professional organization. The DWC was granted divisional status in late 1981, with its bylaws accepted in 1983 and its first board of officers elected in 1984. Currently, the division has over 300 members. In 2006, the DWC launched the first issue of its own journal, *Feminist Criminology*, dedicated to feminist research and theory in criminology. While not all the members of the division are overtly feminist, many are. Areas of scholarship cover a wide range of topics, including the roles of both gender and sexual orientation in crime, victimization, and criminal justice responses to crime.

The ACJS is the other national academic organization in criminology. The Minorities and Women section was born during the early 1990s due to a commitment to affirmative action. A constitution was drafted and approved by the ACJS in 1991. The initial planning for long-range goals occurred in the summer of 1992. The section was developed as a more liberal feminist approach to criminology, focusing mainly on issues of diversity and inclusiveness. However, the organization has a large number of feminist members.

Summary

Feminist criminology is a descriptive term for a wide range of topics, theories, and methodologies. There is no unified theoretical approach but rather an emphasis on placing theory and analysis in the framework of male hegemony. Feminist criminologists may utilize mainstream theories in a feminist manner or ascribe to more overtly feminist approaches. Research may be quantitative, qualitative, or both, but it is characterized by reflexivity and awareness of power imbalances between researcher and researched. Feminist criminology examines women as offenders, women as victims, the relationship between victimization and offending, the gendered nature of criminal justice, and women working in the system. Despite the wide variety in approaches, however, the field is unified by a few important points. First, women are normally placed in the center of inquiry. Second, patriarchal society and its role in creating offending, victimization, and work opportunities is considered. Third, activism and emphasis on creating social change through research is emphasized. While some work may embrace only one or two of these, for criminology to be feminist, there must be at least one, and usually more, of these present.

This article is a revision of the previous edition article by L. Obiora, R. Perry, volume 8, pp. 5464–5469, © 2001, Elsevier Ltd.

Abstract

Feminist legal theory manifests through writing and speaking about 'law' and 'women,' in an effort to promote and improve understanding about justice. Feminist legal theory is a set of ideas, an activity engaged in by thinkers in and outside academia, and an intellectual and political movement. Developments in feminist legal theory emerged through engagement with problems rooted in inequalities, experienced by individuals and communities, at the hands of people, corporations, or the state. This article draws out key areas of tension within the field of feminist legal theory, focusing on English-language feminist legal theory and spanning the field of national jurisdictions and international human rights.

Introduction

Feminist legal theory manifests through writing and speaking about 'law' and 'women,' in an effort to promote and improve understanding about justice. Much of that writing and speaking debates the meaning of the terms 'law' and 'women.' Feminist legal theory is a set of ideas, appearing as truth claims, critiques, and/or advocacy messages, an activity engaged in by thinkers in and outside academia, and an intellectual and political movement. In its life span, it has gone through several evolutions, to produce a plural, complex, and fractured body of thought and practice. Evidence for the maturity of feminist legal theory, as a field, can be found in a number of edited volumes and dedicated academic journals. Defining feminist legal theory as a set of ideas and practices situates it across academia, nongovernmental organizations, law firms, think tanks, community groups, and public office. Developments in feminist legal theory have emerged through engagement with problems connected to inequalities, as experienced by individuals and communities at the hands of people, corporations, or the state. The problem-driven impetus of feminist legal theory contributes to its present-day heterogeneity. It also explains how a 'field' of feminist legal theory survives, despite the enduring debates about pillar concepts like 'woman' or 'equality' and resistance to the normalizing and disciplining effects of definition.

The separation line between feminism and feminist legal theory is porous. While feminist legal theory takes law as a primary focus, the whole field of feminist studies regularly engages legal issues because the state is central to feminism's reformist agenda. Contemporary Western feminism's roots lie in nineteenth-century campaigns to abolish slavery and secure the right to vote for women and enslaved people. Although some US campaigners fought to end both slavery and women's oppression, the post-Civil War movement for women's suffrage splintered over decisions to prioritize the voting rights of white middle-class women.

As an intellectual and political enterprise, feminist legal theory has been a movement embedded in the political currents of its time. The twentieth-century's struggle between liberalism and Marxism set the stage for feminist debates about prioritizing civil equality rights over material inequalities. The contemporary rollback of the welfare state, the foregrounding of the nuclear family as the caretaker of human vulnerability, and the disproportionate impact of austerity policies on marginalized women provide the context for the critical attention among feminist legal theorists to issues ranging from the feminization of the global care market to the queer critique of same-sex marriage.

Though feminist theory and activism gained strength into the twentieth century, it was not until the 1970s that 'feminist legal theory' came to be labeled as a field, with different schools of thought appearing and receding over time. Six strands are signposted here and developed further throughout the article. The equality stage of feminist legal theory, sometimes labeled 'liberal feminism' (1) and dated to the 1970s, focused on formal inequalities between women and men and called for ending legal discrimination. By the 1980s, radical or dominance feminism (2) and difference feminism (3) shifted attention to the differences between women and men and the social production of inequality. Both schools of thought were criticized for single-minded attention to the concerns of class- and race-privileged women. An antiessentialist movement (4) introduced thinking and action on multiple and intersecting forms of discrimination. Postmodernism (5) turned attention from dichotomous and categorical identities toward questions of social construction and subjectivity. Queer legal theory (6) challenged foundationalist understanding of sex and sexuality.

This article addresses English-language feminist legal theory in North America, the UK, and Australia, with some additional international representation by authors writing in English. It draws out key areas of tension within the field of feminist legal theory oriented toward domestic and national jurisdictions, and then surveys the state of critique in international human rights.

Method and Epistemology

Feminist legal critique typically starts from the position that understanding material, structural, and ideological conditions requires an attention to sex and gender and their interaction with other axes of differentiation. A common analytic technique focuses on exposing features of an issue that other

methods overlook, by, for example, identifying the gender implications of rules and practices that seem neutral (Bartlett, 1990). However, some critics reject the idea that feminist analysis constitutes the addition of a 'gender lens' on some 'social real' defined on other primary material, ontological, or legal grounds (Morgensen, 2012).

Feminist legal theory has responded to concomitant shifts in legal scholarship and feminism. First through legal realism, then through law and society research and critical legal studies, the gaze of common law scholars turned from the theoretical ideal of law on the books and toward the law in action. While the new empiricism brought concern for making law more effective, it also challenged the hermetic seal between 'law' and 'society' and introduced the notion of the coconstitution of the law, society, and the subject.

Feminist theory traversed similar epistemological terrain. Liberal feminist legal theory revealed the male bias in formal law and legal processes and argued for the reform of law from a neutral perspective. Radical feminists exposed law's neutrality as a patriarchal sleight-of-hand. According to MacKinnon, male dominance's "point of view is the standard for point-of-viewlessness; its particularity the meaning of universality" (MacKinnon, 1989: pp. 116–117). A critique based on standpoint theory argued that this quest for neutrality presumed a view from nowhere – and that there can be no such thing. Rather, a truth could best be reached by treating women as authorities about their own lives and experiences (hooks, 1989). Feminist legal theorists seized the invitation to listen to women's voices in the legal arena, by, for example, analyzing how trial processes heard and shaped women's narratives of violence (Sheppard and Westphal, 2000) or thinking about whether women bring a unique perspective to judging (Minow, 1992). The epistemology of postmodern feminism questioned the whole project of an authoritative perspective on truth, calling instead for a nonfoundational, nonessentialist analysis. Mariana Valverde challenged the law's claims about the unity and coherence of categories like the 'legal subject,' and instead studied the law as a site for discourses and processes that shape what is taken as knowledge (Valverde, 2003). Feminist legal theory also drew on queer theory, a scholarship that postures itself against, or at variance with, the normative. According to queer legal theorist Adam Romero, by jettisoning foundational epistemologies in favor of a positionality consistently opposed to the norm, it becomes difficult to "know definitively what feminist legal theory and queer legal theory, as such, substantively are or do" (Romero, 2009: p. 197). Thus, an attention to epistemology exposes the challenges of the bases of feminism as a political and critical project.

The Human

The human is the starting point for most feminist legal theory. The field of posthuman feminist legal thought reaches beyond the human to nonhuman life, the environment, and the material. Ecofeminism challenges traditional environmental law (Rochette, 2002). Maneesha Deckha has argued that understanding animal oppression is essential to both understanding human forms of oppression and developing a coherent concept of justice (Deckha, 2006). Materialism was largely thrown out with the Marxist bathwater of the late twentieth century (Conaghan, 2013), but feminist scholars drawing from Science and Technology Studies are bringing the material back into view, exploring the enmeshment of mind and body, nature and culture, and human and nonhuman forms of agency (Conaghan, 2013). For example, ultrasound allows us to 'see' a fetus on a screen, an intermingling of machine, body, and senses that informs ideas of the fetus as an autonomous human life (Barad, 2007). The turn to materiality provides a new lens in the debates among feminist legal scholars on abortion and reproductive technologies.

Equality

Because US law historically established and upheld gender inequalities, American liberal feminists took to the courts to dismantle them. Explicit distinctions between men and women were the target of the Equal Rights Amendment, a proposed amendment to the US Constitution that aimed at invalidating gender-biased statutes and common law rules. Though ultimately not passed into law, the goals of the Equal Rights Amendment took effect through litigation led by the Women's Rights Project at the American Civil Liberties Union. Its lead litigator, Ruth Bader Ginsburg – who later became a US Supreme Court justice – fought a line of cases that attacked gender differences in the law, whether they served to harm women or men (Chamallas, 2003). On her understanding of equality, equality under the law required treating like persons alike and unlike persons alike.

The campaign for neutrality in legal standards ran aground when it reached situations where women and men seemed not to be similarly situated, like in scenarios involving pregnancy or physical strength. Some judges thought that pregnancy might be a 'disability'; others argued it was sex-specific and deserved 'special' treatment (Littleton, 1987). Courts, legislatures, and activists attempted to define a 'normal' standard against which 'difference' could be identified (Scales, 2006). The trap lay in framing equality as either sameness or difference and taking men as the standard referent for such difference.

A critique of this binary approach led to a redefinition of equality beyond purely formal terms. Debates about substantive equality reintroduced Marxist questions of the distribution of material resources. From within a liberal rights perspective, courts worried about the limits of a state's responsibilities to provide minimal guarantees or standards of living, with courts frequently deferring to legislatures on questions about redistribution of wealth (Cossman and Fudge, 2002).

Theorists reframed the equality debates as a debate about the meaning of justice. Building on the work of liberal philosopher John Rawls, some feminists argued that if justice is about distribution, then injustice is about the imperfect distribution of material resources, rights and liberties, and opportunities. Communitarians argued that just distribution should include attention to culture and community. Martha Nussbaum advanced a capabilities approach, focused on identifying the minimum conditions that states must provide to ensure human flourishing (Nussbaum, 2000). Carol Gilligan, a leading thinker of difference feminism, introduced the distinction between an ethic of care, in which moral judgment is based on context, relationships, care, and connection, and an ethic of justice, in which judgment

proceeds from abstract principles, rights, and individual autonomy (Gilligan, 1982). Though Gilligan's model has been criticized because it associated men with an ethic of justice and women with an ethic of care, it opened up a field of inquiry about feminist understandings of justice.

Nancy Fraser observed that these opposing views all depart from the 'justice as distribution' paradigm, as neither theory of justice emphasizes transformation or makes an effort to "restructure the underlying generative framework" (Fraser, 1997: p. 23). She argued for a transformative understanding of justice, so that the processes that produce injustice, rather than their effects, can be analyzed and tackled.

Difference

'Difference' signals the categories and lived experiences that are raised, interpreted, and used to produce divisions among people. Difference has been a central challenge throughout feminist legal theory.

In the history of feminism and feminist legal theory, race has arguably been the oldest, thorniest difference. Since the late nineteenth century, women of color have questioned feminism's prioritization of the concerns of white, upper-class women. Early feminism's focus on formal equality in public life and the workplace was criticized for its inadequate attention to the conditions of material inequality experienced by poor and racialized women. Feminists of the 1980s were criticized for essentializing the category 'woman,' whether they preferred ending patriarchal domination or celebrating women's unique gifts. Both law and feminist legal theory had failed to theorize women of color's experiences of discrimination along multiple axes of identity. Kimberlé Crenshaw introduced the concept of intersectionality to challenge the default whiteness of feminist analysis (Crenshaw, 1991). Legal tests often require categorizing harms based on 'race' or 'gender,' with the result that some plaintiffs fall between categories, while others receive no legal recognition of the compounding interactions among different forms of discrimination (Williams, 1987).

Could there be a feminist movement if the category of woman was infinitely fractured along plural lines of identity? This crisis within feminism took place during the apogee of identity politics and the emphasis on multicultural tolerance. Political theorist Susan Moller Okin suggested that multiculturalism was "bad for women" (Okin et al., 1999). Wendy Brown (1995) and Leti Volpp (2001) cautioned against a feminism that depicted women as passive victims of intrinsically oppressive 'culture.'

The synergies between feminism and the global war on terror positioned culture, gender, and sexuality as productive sites of state power. The US nonprofit Feminist Majority Foundation campaigned against the Taliban's treatment of Afghan women, launching what became a simple, media-friendly rallying cry for a deeply complex US war in Afghanistan (Hirschkind and Mahmood, 2002). In 2010, a public controversy erupted when Gita Sahgal, the head of Amnesty International's Gender, Sexuality, and Identity unit, resigned in response to the organization's partnership with Moazzam Begg, a former Guantanamo detainee and UK citizen with ties to the Taliban. Some read Amnesty's collaboration as a welcome attempt to repair relations with a demonized Muslim population, while others, including Sahgal, interpreted it as a threat to Amnesty's core values of equality and universal human rights (Gopal, 2013).

Legislators and judges in the West wrestled with the state's interface with a nonsecular 'other,' on issues ranging from Muslim veiling to the incorporation of religious law into family law disputes (Fishbayn, 2008). Some feminists are deeply troubled by 'accommodation' and integration of the so-called cultural norms in state law, as this is interpreted as ceding ground to rising religious fundamentalisms – both Muslim and Christian. Other feminist legal theorists consider this a welcome step in exposing the white, secular, patriarchal bias of Western law (Fournier and See, 2012). While many feminist critiques focused on race, gender, and religion, other voices called attention to the heteronormative underpinnings of these debates. For example, queer theorist Jasbir Puar studied the connections between the West's war on terrorism, nationalism, and gay rights discourse. Puar argued that the West contrasts its tolerance of homosexuality and its concern for the vulnerable Muslim queer to a demonized Middle Eastern masculinity, thus justifying Western Islamophobia and fueling a belligerent homonationalism (Puar, 2007).

Law

Feminist legal theory often aligns with the canonical categories it challenges, resulting in feminist critiques of contract, criminal law, tort law, tax law, and so forth (Bottomley, 1996; Brooks, 2011). An alternative approach is problem-based, producing bodies of scholarship and activism around categories like reproductive justice, sexual and gender-based violence, workers' rights, and the criminalization of poverty and migration (Bridgeman and Millns, 1998; Schneider, 2000; Conaghan and Rittich, 2005). These efforts map the ways that law intersects with women's lives, fails to respond to women's realities, shapes their opportunities, and constructs their sense of self. 'Law in action' studies inquire about the law's simultaneous role in constructing disadvantages, remedies, identities, and understandings of justice, as in Catherine Albiston's research on the effects of the US Family and Medical Leave Act in changing the behavior and values of employers and workers (Albiston, 2010). A canonical example of the feminist analysis of legal doctrine is Catharine MacKinnon's study of rape law, which shows how rape law starts from a male point of view (MacKinnon, 1983). A further approach connects feminist theory to philosophical debates about rights. Frances Olsen, for instance, warns against a turn to rights for the purpose of women's emancipation. She argues that the resolution of conflict in rights terms can oversimplify complex power relations, deprive conflicts of their political significance and force, and fail to take into account structural power inequalities (Olsen, 1984). Through this engagement with law, feminist legal theory has unseated the neutrality of law's foundations.

Feminist legal theorists take a range of views about what law 'is' and what prospects it offers for achieving the goals of feminist reformers. Liberal feminists, most concerned with formal inequalities, define the law as residing in cases and statutes and implemented by lawyers, judges, and legislators. Departing from the view that the law is fundamentally

grounded in fairness, proponents like Ruth Bader Ginsburg believe that the law could be reformed to better respect 'women's' rights.

Radical feminists, attentive to power relations, are less sanguine about the nature of law and its potential for positive social change. They find the law in the inert words of statutes and cases, but also in norms, habits, and entrenched attitudes. Typified by Catharine MacKinnon's work (MacKinnon, 1983), these scholars see the law as embedded in patriarchal, stratified social relations. The law is susceptible to reform through feminist litigation and campaigning, but it is highly resistant to change. For example, in her work on domestic violence, Reva Siegel has shown how law is more liable to continuity through transformation than to genuine reform (Siegel, 1997).

Postmodern theorists adopted a multidimensional view. For example, for Carol Smart, although the law is defined as a socially powerful place for producing knowledge claims about justice and distribution, it is not universally or intrinsically helpful or harmful to the subjects who seek its remedies (Smart, 1989). Queer critics like Janet Halley raise concerns about the law as an institution premised on defining and separating the normal from the deviant, thus casting doubt on the role of law in emancipatory political projects (Halley, 2006).

State

Feminist legal theorists disagree about the nature and role of the state in emancipatory political projects. For liberal legal theorists, the state appears variously as a site for protection, a guarantor of individual rights and liberties, an agent of limited redistribution, a legitimate source of punishment, and an arena for fair debate. On this view, the state's laws are open to change through legislative or judicial processes (Davies, 1994).

Difference feminist theorists are skeptical about reforming the neutral state. Since women and men are fundamentally different, with different starting points in life and different needs, reform efforts are best focused on remedies like affirmative action, quotas, maternity leave, and public child care (Nott, 2000; Gilligan, 1982; Davies, 1994). These differences aside, both liberal and difference theory envisioned a strong state at the helm of justice projects.

These understandings of the state were challenged through the influence of Marxism and postmodernism. It became less fashionable to see the state as either a positive or negative space for feminist engagement.

Radical and postmodern feminist theory draws on these insights. According to radical feminist theorists and their readings of Marx, the very idea of a line between the state, the market, and the family manufactures the zones of state noninterference – in contractual relations and family relations – that expose people to patriarchal and capitalist violence (Olsen, 1985; Rose, 1987). Postmodern feminism, influenced by philosopher Michel Foucault, describes the state as a site for the production of discourse, with normalizing and disciplinary effects caused by self-governance rather than overt coercion or domination (Boyd, 1997). From this perspective, every choice by the state is a form of regulation; even a decision to 'do nothing' is a regulatory decision, because the practical consequence of 'nonregulation' is a normalization of existing distributions of power and resources.

More recently, the analytical lens has broadened, the state has been decentered, and a plurality of sometimes contradictory, context-driven views have emerged. Many contemporary theorists treat the nation-state as one of many spaces in diffuse local and global assemblages of power. Janet Halley's concept of governance feminism describes the installation of feminists and feminist ideas within institutional and legal power (Halley, 2006). Those fighting to end gender-based violence in intimate relationships push for a stronger police force, swifter prosecution, and mandatory sentencing (Kelly, 2005). Other theorists advocate for considerably 'less' state – for example, those concerned with the criminalization of poverty, swelling prison populations, violent working conditions of sex workers, and life chances of trans people (Spade, 2011; Bumiller, 2008).

Freedom

Complex debates over the notion of freedom course through feminist legal theory, bringing in their wake questions about agency, power, choice, and the nature of the subject. As Marx discussed in his classic essay "On the Jewish Question," the state's abolition of formal distinctions based on birth and the decree of individual equality leaves untouched all the material, cultural, and social structures of domination. Liberalism's vision of freedom is synonymous with formal equality rights. Equating freedom with equality rested on the introduction of the abstract, liberal, self-sufficient universal subject (Fineman, 2004).

This liberal subject is the object of concerted study across feminist legal theory. Liberalism's canonical accounts start with a natural, unified, and autonomous (implicitly or explicitly male) individual who yearns for a social world in which he can pursue his self-interest. Feminists disagree with this model, arguing that the self is neither a preconstituted individual nor wholly determined by membership in a social group. Rather, the subject is socially constructed and constituted relationally, through involvement with – and incorporation of – significant others and integration into communities (Young, 1990).

Discarding the idea of any essential or natural identity, Judith Butler argues that "woman itself is a term in process … an ongoing discursive process" (Butler, 1990: p. 33). Gender identity is performed, as opposed to intrinsic or natural, and "genders can neither be true nor false, but are only produced as the truth effects of a discourse of primary and stable identity" (Butler, 1990: p. 136). On this account, the body does not preexist as a biological 'real,' but is itself materialized through discourse.

Considering the subject as the effect of ongoing social processes and discourses muddies the waters of freedom and agency. How do people know what they want if there is no core, autonomous self who directs decisions, their available choices are constrained by material realities, and their wants and desires are shaped by social conditions?

Commercial surrogacy contracts offer an example of such dilemmas. It was the absence of choice that led radical feminist Andrea Dworkin to compare surrogacy to prostitution (Dworkin, 1983), while Christine Overall questioned whether the choice to enter a surrogacy contract could be a free one

(Overall, 1987). On the other hand, some feminists argued that commercial surrogacy arrangements were in fact the manifestation of a woman's right to make choices about her body and enter into contracts for financial gain (Shalev, 1989). An empirical survey of existing research found that women of color are greatly underrepresented as surrogate mothers (Busby and Vun, 2010). Such empirical findings bolster the argument that respecting women's agency requires attending to their own accounts of their lives and capacities. On issues ranging from surrogates to sex workers to women in military academies, courts, legislators, activists, and theorists have struggled to define women as victims or agents and have debated whether policies should reduce or expand women's field of choices.

Sex and Sexuality

The women's movement spent the 1960s campaigning for reproductive rights like access to abortion and contraception, and the 1970s lesbian feminist movement brought greater attention to women's rights to sexual pleasure with other women. Adrienne Rich denounced feminism for assuming a standard norm of female heterosexuality (Rich, 1980). By the late 1970s, feminists began to emphasize the violence and danger associated with heterosexual sexuality and the late 1970s and early 1980s saw feminist legal theory gripped by the 'sex wars.'

Debates divided many feminists into two opposing positions, often labeled as radical and sex positive. According to the radical feminist point of view, under conditions of patriarchy, sex and sexuality intrinsically perpetuated violence against women. According to a sex-positive point of view, sex and sexuality were sites of personal pleasure and political possibilities for subverting patriarchal definitions of femininity.

The 'sex wars' of the 1980s took shape around an emerging antipornography movement, underpinned by radical feminism and its theory of gender oppression. Radical feminists, such as MacKinnon and Dworkin, campaigned for the use of censorship and other legal prohibitions in order to outlaw pornography and reduce sexual violence against women. Pornography was seen to shape the cultural devaluation of women, define women's sexuality, and eroticize violent relations of domination. Sex-positive feminists reacted to this legal campaigning by decrying sexual repression, calling for greater sexual freedom, and defining sexuality as a site of political resistance.

Sexual practices and the meaning of consent were focal points of disagreement. For radical feminists, pornography, prostitution, sadomasochism, and sexual role-play like butch–femme relationships amounted to the repetitive entrenchment of male dominance. For example, MacKinnon argued that heterosexuality "institutionalizes male sexual dominance and female sexual submission" (1989: p. 113). In contrast, sex-positive feminists supported consensual sexual practices and they criticized radical feminists for repressing sexual desire and stigmatizing sexual minorities. Carlin Meyer argued for a brand of sex-positive feminism that could theorize sexuality as a space for autonomous and liberating choices (Meyer, 1994), while Robin West called for theories of sex as valuable to women's subjective well-being (West, 1987).

Questions about consent also underpinned these debates. For radical feminists, there could be no authentic consent or agency in a world of choices defined by male dominance and violence. In contrast, sex-positive feminists viewed women as capable of consenting and exerting agency and they criticized radical feminists for defining women's identities as effects of male domination (Abrams, 1995). However, this work was slow to percolate into legal theory. Katherine Franke commented that feminist legal theorists, "have done a more than adequate job of theorizing the right to say *no*, but we have left to others the task of understanding what it might mean to say *yes*" (Franke, 2001: p. 181).

The heated debates about sex and sexuality in the 1980s generated both divisions and new political formations. Gayle Rubin argued that feminism had little to say about sexuality, notwithstanding its expertise on gender-based subordination (Rubin, 1992). Eve Kosofsky Sedgwick said that gender and sexuality were distinct analytic axes – and distinct intellectual arenas (Sedgwick, 1990). Their argument for a new intellectual terrain, beyond the sex/gender distinction, gave birth to the field of queer studies.

Through engagement with queer theory, feminist legal theory has moved toward an increasingly antiessentialist understanding of sex and gender and a more diverse account of sexuality. Theorists, including Judith Butler, opined that people were born with a biological sex, but acquired a self-conception of gender through processes of socialization (Butler, 1990). This insight severed the 'natural' or 'inherent' from the socially contingent, so that the socially produced could be legally and politically challenged. Queer theorists argued that sexuality was also socially produced and culturally constructed. Queer legal theorists challenged the law's reliance on a male/female binary. They argued that a multiplicity of sexes, genders, and sexualities exist along a spectrum. In recent years, some trans legal advocates have celebrated the legal permission to move across the male/female divide, while others argue for a world that accepts the 'in-between' reality of the trans-gendered, intersexed, bigendered, and androgynous (Cowan, 2013).

While sexual minorities and dissidents achieved some equality gains in the late twentieth and early twenty-first centuries, the story of progress nevertheless rests on an economy of normal and deviant, included and excluded. Campaigners applauded the legal recognition of same-sex marriage as a victory for formal legal equality, but others saw the same-sex marriage project as yet another instance of the yearning for recognition by a state, and with it, the attribution to the state of power to police everyone's sexualities (Spade, 2011).

Marriage and Social Reproduction

Marriage and social reproduction have been sites for the formation and consolidation of state authority. The law's construction of the private sphere as an autonomous realm served to uphold and generate gender subordination. Key themes have included the rights to bodily autonomy, choice, privacy, and the public/private divide.

Under the common law doctrine of coverture, a married woman was located under the authority and protection of her husband, preventing her from making contracts or wills, controlling her earnings, or owning real property. In the nineteenth century, in the United States, the state regulation of

marriage permitted the definition of a private sphere, shielded from state intervention. As informal, *de facto* marriages were brought into the formal institution of marriage, people were legally bound in defined obligations, thus widening the scope of state authority. Incorporating more relationships – including the nonnuclear families of freed slaves – into the institution of marriage ensured that dependents would be the responsibility of husbands, rather than the state. A gender ideology of 'separate spheres' emerged, in which each sex had different natures with unique and complementary moral attributes. Post-Civil War married women's earning acts gave a married woman property rights in her own labor, while simultaneously defining household labor as an obligation of marriage, rather than a form of work (Cott, 2000).

Feminist legal theorists challenged the public/private divide enshrined in the regimes of coverture and separate spheres ideology. The US feminists leveraged the constitutional right to privacy as a route to contraceptive sales and abortion, but they also sought to pierce the shield of privacy around the marital home to compel state intervention in domestic violence.

Feminist legal theory challenged the role of law in creating and upholding the heterosexual family as the setting for the distribution and fulfillment of natural and inevitable dependencies. Activists in the 1970s demanded wages for women's domestic work and pointed out that 'free' care work in the home creates, sustains, and subsidizes the labor force. According to Martha Albertson Fineman, "the sexual family is considered the 'natural' form for the social and cultural organization of intimacy, its form ordained by divine prescription and perpetuated by opinion polls" (Fineman, 1995: p. 143). Approximately, 70% of families in 1940 fit the traditional male breadwinner–female housewife model; by 1988, however, the so-called traditional families accounted for only about 20% of all families and today there is no longer a typical or dominant family form (Albiston, 2007). Nevertheless, the ideology of the nuclear family defines both normal and deviant configurations of social reproduction. A vibrant literature has emerged in recent years, studying the globally distributed care economy and the resulting alliances and conflicts of interest between and among women in the global North and global South (Williams, 2000; Johnson, 2002; Conaghan and Rittich, 2005).

Feminist Legal Theory and International Human Rights

Feminist critiques of international human rights can be divided into three categories: (1) normative and institutional calls for the inclusion of women into human rights, (2) study of the role of gender in the architecture of the human rights system, and (3) critique about the perils and pitfalls of human rights.

The statement that "Women's rights are human rights," from the 1993 Vienna World Conference on Human Rights, confirmed the migration of women's interests from the isolated backwater of 'special issues' into the mainstream of human rights (Friedman, 1995). Fields of feminist activism and critique include development, transitional justice, international humanitarian law, peace and conflict, violence against women, reproductive and sexuality rights, refugees and migration, and international economic policy (Askin and Koenig, 1999). Christine Chinkin and Hilary Charlesworth observe that while there has been much feminist critique of the use of rights at a domestic level, there has been relatively little feminist critique of the normative and tactical value of human rights at an international level (Charlesworth and Chinkin, 2000). Their explanation is that feminists have been hesitant to critique what is so new and so hard-won, echoing Patricia Williams' comment that, from the African-American perspective, "rights feel so new in our mouths" that they should not be impugned (Williams, 1987).

The first generation of feminist critique of human rights sought to explain why women were excluded from the protection of human rights and what had to be done to remedy this. One explanation was that there were no 'general' human rights; by this reckoning human rights are, in themselves, men's rights (Charlesworth, 1995). State sovereignty has been theorized as an extension of masculinity in the international sphere (Ruskola, 2010), while the primacy given to civil and political rights over economic, social, and cultural rights has been explained as a source of women's exclusion from human rights protections (Sullivan, 1995).

Another body of empirical scholarship illuminates the ways that gender appears in the architecture of contemporary human rights and their antecedents. During the founding of the United Nations, founders were unwilling to grant rights to women specifically, but they saw gender as a metric of development. In the newly formed United Nations, the status of women in territories administered by member states was a key indicator of a country's capacity for self-governance (Knop, 2002).

A third body of critique invited caution about the feminist project in international law. In line with the "Third World Approaches to International Law" movement, this new literature exposes the complexities, distorting conditionalities, and unintended consequences of feminist gains in international law (Chinkin et al., 2005; Otto, 2006). First, scholars note that the feminist human rights movement imagines the international as an imaginary and utopian site of justice. International elite human rights advocates (from both the North and South) construct the particular as the problem in order for the universal to be the solution, while simultaneously avoiding the injustice born within the international economic and political system (Nesiah, 1993).

Second, theorists study the effects of injecting feminist principles into international institutions. Examples of governance feminism in international law include the recognition of sexual violence crimes in international criminal law and a focus on the criminalization of sex trafficking (Halley et al., 2006). Although feminists have achieved goals like gender mainstreaming in international law, the institutionalization of feminism in international law has adverse effects.

Third, the ascent of women's rights, primarily driven by campaigning on violence against women, was conjoined with the demonization of culture as an intrinsically oppressive force. Ratna Kapur has criticized the ways that international law rests on an essentialized understanding of gender and culture, which combine to produce a 'helpless' native victim of human rights law (Kapur, 2002). Sally Engle Merry has shown how UN rights

processes adopt a static definition of culture, which is then counterposed to make universal claims for gender equality (Merry, 2006). For Leslye Obiora, the international and First World obsession with culture obscures the primary cause of women's rights violations: global inequality and structural economic exploitation (Obiora, 1997). From such a perspective, human rights and feminism might well be Trojan horses. They may bring some gains for women's equality and well-being, but other, new harms, like the demonization of culture and disregard for global material inequalities, might creep in as well.

Conclusion

Recent surveys about the state of the field in feminist legal theory have produced numerous edited volumes – signaling the field's depth and diversity – while at the same time sparking reflection about the dispersal of the field, due to productive recentering around key words like sexuality or masculinity or the mainstreaming of its key analytic concerns across mainstream legal scholarship (Abrams, 2011). Discussions about the health of the field reveal the character of feminist legal theory as a movement that provokes deep personal investments, rather than as an arms-length academic exercise. Scholars who are seen to have harmed the feminist legal project, as though it were a mortal being, risk extreme vitriol. Janet Halley's (2006) suggestion to "take a break from feminism" provoked such a reaction (Halley, 2006). Halley defined legal feminism as reliant on a gender polarity between women and men, a subordination of women to men, and a commitment to acting for women. This account, according to Halley, both diminishes feminist victories and glosses over the casualties on the way to power. For some, Halley's invitation was tantamount to apostasy. Although feminist legal theory has matured, diversified, and become more plural, there remains the belief that there is a battle to be fought, and some speech and action count as crossing enemy lines.

Critique today seems to require moving across the confines of jurisdictions – both national and intellectual – and abandoning monolithic theories of the state and single-method studies. As a field that has, from its inception, convened a rebellious rabble of activist and theoretical voices, feminist legal theory is experienced in crossing boundaries. One such boundary separates the humanist and the empirical. Political theorists, rather than feminist legal theorists, led the way in debates about the meaning of justice. This is surprising given legal theory's penchant for normative questions, but less surprising given that feminist legal scholars have devoted their energies to empirical investigation into the 'impact' of law on women and analysis aimed at winning legal victories by exposing the 'true' gendered nature of law. According to Marianne Constable, questions about the meaning of justice may be occluded by accepting the model of a world that 'is' and a law that 'does' things and 'tells' people what to do (Constable, 1994). The next chapter of feminist legal theory could attend to life – in all its pluralities – as it ought to be or could become.

This article is a revision of the previous edition article by J. Lovenduski, volume 8, pp. 5475–5478, © 2001, Elsevier Ltd., with an updated Bibliography supplied by the Editor.

Abstract

Feminist scholars have shown that few aspects of politics are unaffected by gender. The feminist study of politics is interdisciplinary and radical. There are three main dimensions to this critique of politics: feminist political theory which is predicated on a critique of contemporary liberalism, challenges the conventions of political theory; feminist political science, a critique of political institutions and the ways they are typically understood; and feminist accounts of gender and politics that combine explorations of gender as a category, as a hierarchy, and as performance in studies of how gender relations are implicated in power. In the study of politics, feminist use of the concept of gender involves redefinition of the split between public and private life and the re-examination of conventional political science for gender dimensions in order to construct a gender informed understanding of politics.

In popular discourse the term feminism is normally used to mean support for women's rights, while a feminist is someone whose central concern is with the position of women and their struggle for emancipation (Delmar, 1986). The definitions are contested by feminist scholars and subject to change. In the 1970s feminism was frequently defined as opposition to the dominance or subjugation of women. By the end of the 1990s it was impossible to define feminism without reference to the concept of gender and it was unusual to refer to feminism in the singular. Feminisms are therefore standpoints. They are also political practices (most often social movements), and sets of ideas and theories. To complete the definition it is necessary to add the concept of gender. Gender is a category that was developed to explore what counts as 'woman' and what counts as 'man' (Squires, 1999, p. 54). Thus, one useful definition of feminisms declares them to be oppositions to gender hierarchy, capturing the different situations and interests of different women in the pluralization of 'feminism,' while the social construction of masculinity and femininity is signaled by the term 'gender.'

Gender Studies and Feminist Scholarship

Challenging the approaches and preoccupations of mainstream scholarship has proved to be a continuing focus of feminist politics. Originally mainly concerned with 'women's studies,' the attention of feminist scholarship gradually shifted to the study of gender and especially to gender relations and the nature of masculinity and femininity. Feminist writings include critiques of most areas of contemporary scholarship calling into question their sensitivity to issues of gender. The shift had important implications for the social sciences including the study of politics. In the social sciences an important feminist concern is to establish the category of gender as a fundamental social division. The feminist critiques of political science are part of this tendency, addressing the standard themes of research on politics, questioning narrow definitions of the 'political,' and also drawing upon research and thinking about gender in other disciplines.

Feminist political science is therefore interdisciplinary and radical, offering a broad definition of the field. Feminist political studies take three main forms: (1) feminist political theory which is predicated on a critique of liberalism and challenges the conventions of political theory, (2) feminist political science which is a critique of political institutions and the ways they have been understood, and (3) feminist accounts of gender and politics which combine explorations of gender as a category, as a hierarchy, and as performance in studies of how gender relations are implicated in power. Each area is work in progress, complicated and contested. Similar patterns of development have characterized each of the three kinds of discussion.

Feminist Political Theory

The women's liberation movement of the 1960s and 1970s gave a new impetus to feminist politics. This was at first new social movement politics, suspicious of formal hierarchical organizations which were regarded not only as undemocratic but also as sexist. However, feminism was, and is, profoundly political. The early slogan 'the personal is political,' questioned the nature of power and challenged the conventional restriction of politics to the 'public sphere.' Initially, feminist political theory was a matter of unmasking sexist assumptions and the neglect of women by Western Political Theory. Carol Pateman argued that the subjugation of women was a central underpinning of modern political thought and that gender difference made a public sphere possible at the expense of women. She contended that the distinction between state and civil society is only visible if the family is ignored. If civil society is labeled private then family is forgotten in political discussion (Pateman, 1988). Hence the addition of women to the concerns of political theory brought the central assumptions of liberalism into question, notably the separation between public and private life.

Recognizing that writing gender differences into political theory required a major reconsideration of political ideas, feminist theorists addressed issues of equality, justice and

representation, initiating debates that grew increasingly sophisticated. Originally theoretical arguments were built around binary oppositions or dualisms such as equality/difference, nature/nurture, justice/care, inclusion/exclusion, all thought to parallel male/female dichotomies. Arguments in the equality/difference debates considered whether men and women should be treated the same or whether differences should be taken into account in order to treat both fairly. The justice/care debates addressed a perceived difference between an ethic of justice (in the liberal distributive sense) and an ethic of care (in a maternalist sense), argued to be male and female, respectively.

Representation arguments considered whether women need women to represent them, reasoning that the identity of the speaker matters to the interpretation of what is said (Phillips, 1995; Young, 1990). Discussions of justice, equality, and representation tended to converge into arguments about citizenship in which feminists seek to redefine politics in terms that integrate public and private concerns, breaking through the public/private divide (Dietz, 1985; Mouffe, 1995; Lister, 1997). Since the 1980s a tendency to contest the oppositions has become more prevalent as theorists seek to transcend or displace the hierarchies, often by redefining issues and concepts (Squires, 1999, pp. 226–33).

Feminist Political Science

Although there were very few links with feminist political theory, feminist political science has followed a similar trajectory, developing from the inclusion of information about women to the subject matter of politics to an intellectual concern to establish a gendered discipline. Feminist political science first sought to eliminate the 'bad science' of exaggerating and misconstruing differences between women and men, assuming a male political universe and using data without their original accompanying qualifications. They were troubled by the distortions present in the mainstream of behavioral political science arising, they believed, from an epistemology that separated facts and value and privileged so-called value-free factual accounts. The effect of concern only with putative facts was to allow behavioral political science to factor women out of consideration as political subjects. An overemphasis on measurable political behavior prevented recognition of '… not only the … exclusion of women from what is traditionally political, but also the inclusion of politics in what women have traditionally done' (Nelson, 1989, quoted in Carroll and Zerilli, 1993). Families, communities, and voluntary groups all went largely unresearched as constitutive of political life. Inevitably, feminist political scientists sought to expand definitions of politics, lending strength to other challenges to overconcern with electoral behavior and elite participation, at the same time as examining differences in men's and women's political behavior. Discussion of the significance of the public/private split and the confinement of women to the private realm were an important challenge to narrow constructions of political power. So too were studies of the crucial part played by the state in regulating sexuality (see Carroll and Zerilli, 1993; Lovenduski, 1998).

Once it was necessary (and possible) to study the effects of women on previously male-dominated political institutions and organizations, the need for an adequately theorized notion of gender was accepted. As increasing numbers of women appeared in legislatures, councils, and other representative bodies as well as in executive organizations and public administrations of various kinds, a considerable debate developed about the causes, stability, and results of gender differences in political activity. An especially powerful line of argument for both feminist activists and their opponents was the contention that women should not seek equal presence to men in powerful positions because they would be 'incorporated' and changed by it, they would become unable to represent women because they had been turned by male created institutions into political men. The counterclaim was that once a significant number and diversity of women occupy decision making positions in previously 'masculine' institutions they would be transformed, their gendering altered.

This argument, so important in feminist debate, has echoes in the conventions of the study of political processes (Randall, 1991). Once arrangements, practices, and rules are institutionalized, actors learn them, invest in them, and make decisions accordingly. Particular institutions become associated with particular behavior and outputs that may be classified as masculine or feminine (Duerst-Lahti and Kelly, 1995). The practices that insulate the positions of typical members and are notoriously difficult to change are gendered.

Feminism and Gender Studies

Feminist intellectual concern about women and power generated research in the arts, humanities, and social sciences. In the fields of history, sociology, social psychology, literature, and cultural studies, a substantial body of work about different aspects of gender and power was produced. In addition a significant field of 'new' men's studies examined masculinity as a category both of privilege and oppression (Carver, 1996). Analysis of masculinities has also received considerable attention from feminist theorists who also claimed that differences among women were at least as important as differences between women and men, that race, class, age, ethnicity, sexuality, and physical ability were, like sex, constitutive of political identity and therefore of political behavior and power.

Feminism, Gender Studies, and Political Science

When feminist political scientists contested narrow definitions of politics, it was because they wanted to expand their research to aspects of 'private' life and to examine the role of government and the state in constructing and enforcing certain kinds of relationships between women and men. As it became more widely understood that both women and men have gender, debates across disciplinary boundaries became a common feature of feminist research on politics. Once perceived, the effects of gender cannot be left to one side or held constant for the sake of other experiments. As it has come to be defined, gender is embedded in individuals, relationships, institutions, and organizations. The gender debates are part of a continuing

process of definition refinement and theory production that enhances understanding of political institutions and processes. A 'gendered' political science looks 'not just at particular theories and assumptions as they have been applied to women, but as they are constructed and apply in any case' (Sapiro, 1991). Institutional research traditions in political science require the close description of contexts, norms, processes, and cultures to which a gendered vocabulary may be applied. It follows that the gendered interests present in political arrangements should be acknowledged and analyzed.

In summary, feminist scholars have shown that it is difficult to think of an aspect of politics that is unaffected by gender. However, gender is not a neat and tidy concept to be slotted into unchanging research strategies. Using the concept of gender involves rejection of the definitions of politics implied by the conventions of the public/private split, re-examination of the productions of conventional political science for gender dimensions and, on that foundation, the construction of a political science that is gender informed.

Abstract

This article reviews the basic tenets of feminist psychotherapy, its history and core values, techniques, and approach to integrative psychotherapy. Originally an approach that focused primarily on the concerns of women, feminist psychotherapy has increasingly emphasized the needs of all people and their multiple identities related to race/ethnicity, gender, sexual orientation, nationality, culture, age, disability, and other social identities. Feminist psychotherapy is characterized as a living, evolving approach that emphasizes the importance of understanding individuals within their biopsychosocial, ecological, transnational contexts.

Introduction

Feminist psychotherapy has its roots in the civil rights and women's movements of the 1960s. Over the past 50 years, it has evolved substantially and has increasingly transformed psychological practice. For example, the American Psychological Association's (APA, 2007) *Guidelines for Psychological Practice With Girls and Women* reflects feminist values and reveals ways in which egalitarian and social change values have been incorporated within basic assumptions about optimal psychological practice. Rather than being a specific set of theories or techniques for working with clients, feminist therapy can be described as a superordinate structure or framework that orients a practitioner's worldview and assumptions about what matters in competent and empowering practice with individuals, especially those persons whose experiences have often been marginalized within the culture. Brown (1994) noted that "what makes practice feminist is not who the clients are or the specific techniques used, but how the therapist thinks about what she does" (p. 2).

A feminist psychotherapist draws from a range of nonsexist psychotherapy approaches that can be integrated with feminist values. Thus, feminist therapists are typically technically eclectic, drawing from a diverse range of theoretical orientations such as cognitive behavioral, humanistic, psychodynamic, and family systems approaches. For example, a feminist psychotherapist may describe her or his approach as a feminist multicultural narrative approach, a feminist existential approach, or a multicultural feminist cognitive therapist.

Feminist psychotherapists are informed about the social justice issues within their environments, and continue to refine the meaning of feminist psychotherapy and practice in a changing world. The work of feminist therapists is often integrated with diverse interdisciplinary perspectives (e.g., political science, sociology, philosophy). Feminist therapists define their roles as therapists, advocates, and social change agents who support the holistic empowerment of persons with whom they work.

What is Feminism and Feminist Therapy?

Feminism is defined in *Webster's New World Dictionary* (1978) as (1) the principle that women should have political, economic, and social rights equal to those of men; and (2) the movement to win such rights for women. While this is a relatively benign definition, the range of reactions and beliefs attached to the word feminism is vast and often emotionally laden, with some holding misconceptions that feminists typically reject femininity, are antimale, and define their goals in extreme or inflexible ways. These stereotypes are not consistent with the goals or definition of feminism. Feminist theorist Gloria Jean Watkins, whose chosen pen name is bell hooks (2000), clarified the breadth and depth of feminism when she defined it inclusively as a commitment to ending all forms of oppression that interact with sexism, including heterosexism, colonialism, ethnocentrism, white supremacy, ageism, racism, classism, ableism, and other forms of marginalization. The goal of feminism is to empower all individuals, including men, to create a world in which equality is experienced in individual, interpersonal, institutional, national, and transnational contexts.

The relevance of bell hooks' (Gloria Jean Watkins) definition can be seen in Laura Brown's description of feminist therapy, which appears on her Web site (http://www.drlaurabrown.com/feminist-therapy, see also Brown, 1994): "I define feminist therapy as the practice of therapy informed by feminist political philosophies and analysis, grounded in multicultural feminist scholarship on the psychology of women, men and gender, which leads both therapist and client toward strategies and solutions advancing feminist resistance, transformation and social change in daily personal life, and in relationships with the social, emotional and political environments."

Contemporary feminist therapists adopt an intersectional perspective, which means that in order to understand constructs such as sex, gender, and gender-related biases, it is necessary to understand how gender-related concepts interact with and are informed by other social categories such as race/ethnicity, sexual orientation, sexuality, nationality, culture, class, and religion. Intersectionality also implies that a given individual may experience some social identities that confer oppression (e.g., sexism or classism), and they may also experience some social identities that confer privilege (e.g., white and/or heterosexual privilege). The degree to which one experiences privilege or disadvantage is modified by social contexts, such that an individual may experience privilege in some

settings (e.g., as a middle-class white female leader within a group with other women) and oppression in others (e.g., as a token woman in a corporate environment). Thus, a woman may experience discrimination in the corporate work environment but may perpetrate racist or classist behaviors toward persons with less privileged social status. The experience of marginalization, oppression, privilege, and equality are complex and changeable, adding to the complexity of practicing psychotherapy that focuses on supporting the equality of all people. As a foundation for considering the complexity of power, privilege, and oppression, the integration of multicultural and feminist perspectives is especially valuable.

It is noteworthy that multiple approaches to feminism exist and are defined by terms such as liberal feminism, multicultural feminism, radical feminism, socialist feminism, postmodern feminism, critical race feminism, third wave feminism, and queer theory. Although gender equality is a shared foundation of each of these theories, there are differences among these theories with regard to their assumptions about how and why oppression exists, how inequality can be best eradicated, and how equality should be defined and achieved. Exploration of these diverse approaches helps increase the feminist therapist's self-awareness of values, and provides a foundation for developing a consistent and well-informed philosophical approach that is integrated effectively with compatible psychotherapy techniques.

The Origins and Evolution of Feminist Therapy

The civil rights and women's movements of the 1960s prompted a reconsideration of roles for women and men and other disenfranchised groups in western society. Consciousness raising groups provided a forum for women to make the link between their personal experience and the political and social context in which these experiences were constructed. One of the outcomes of consciousness raising groups was the emergence of feminist psychotherapists who sought to implement the empowering aspects of consciousness raising groups in their work with individuals who experienced problems in living. Over time, feminist therapists integrated the values and practices of consciousness raising groups with nonsexist and antiracist psychotherapy systems.

Early feminist therapists noted that most of the then available theories, research, and diagnostic approaches established the lives of privileged men as normative, resulting in women's experiences or perspectives being seen as deficient in comparison to those of men (Gilligan, 1982). Chesler (1972) characterized the typical client–therapist relationship as establishing the therapist (typically male) as an expert or patriarch, who defined the reality of the patient and often reinforced the unequal status between men and women in the larger culture. Other criticisms and concerns (Worell and Remer, 2003) raised by feminist therapists focused on:

- the general omission of women from the knowledge base of psychology,
- the failure to recognize that psychopathology may reflect power imbalances in addition to intrapsychic and interpersonal difficulties,
- the disregard of many health professionals for women's self-reported experience,
- the practice of attributing blame and responsibility to women for their experience of sexual and physical violence,
- the tendency to pathologize women's interdependence and interpersonal involvement, such as by blaming mothers or characterizing women as interpersonally enmeshed, and
- the practice of medicalizing women's psychological problems, including diagnosing their concerns in narrow terms or overprescribing medications.

As an outgrowth of their concerns, feminist therapists sought to redefine the psychotherapy in egalitarian ways and to emphasize their clients' strengths, resilience, and agency rather seeing them as individuals who merely needed to be cured (Gilbert, 1980). One of the outcomes of this redefinition was the gradual implementation of informed consent principles as standard aspects of all psychotherapy practice. Over time, psychological and social service practice has benefited from an explosion of research and theory about the lives and experiences of diverse women (Hyde, 2013), and this research has provided a strong research foundation for the work of feminist psychotherapists. Another transformative outcome of the work of feminist researchers and practitioners can be seen in the *Guidelines for Psychological Practice With Girls and Women* (APA, 2007; discussed later in this article), which are based on at least 40 years of research and are intended as guides for optimal psychological practice for all psychological practitioners, not only persons who identify themselves as feminist. It is important to note that whether contemporary psychotherapists define themselves as feminist or not, feminist therapy values and assumptions have permeated the practice of those who seek to provide exemplary services to women and men.

Core Assumptions and Principles of Feminist Therapy

Although they may vary in their application, feminist approaches are characterized by the following assumptions: (1) the personal is political; (2) equality and egalitarianism are central to the practice and goals of psychotherapy; and (3) knowledge of diversity, complexity, and intersectionality are necessary for working toward empowerment (Brown, 1994, 2010; Enns, 2004, 2012; Worell and Remer, 2003).

The personal is political (as well as the political is personal) reflects the notion that human concerns cannot be solved in isolation from gender and other identity politics, which often result in women's and other marginalized persons' lower social status and oppression in most societies. Individual concerns need to be understood holistically and within a biopsychosocial and ecological context that considers microsystems, such as the systems and groups with which one interacts on daily basis; exosystems, such as social, governmental, and political institutions and policies that affect one's options and degrees of freedom; and macrosystems, or cultural influences, values, and worldviews (Ballou et al., 2002).

Feminist therapists bring a questioning stance toward status quo understandings of emotional distress, seeking to understand how a client's problems and strengths are related to or

embedded in her or his social milieu. Problems are understood as emerging from efforts to cope with challenges of living. For example, a person who experiences disempowerment may have learned to rely on indirect methods of coping, such as dependency, acquiescence, or manipulation. Although coping efforts such as dependency or acquiescence may support survival in difficult contexts, the costs associated with such strategies are often high and may result in symptoms of anxiety and depression. When these troubling symptoms are reframed as the client's coping skills that have outlived their usefulness, rather than as personal deficiencies, clients are more likely to move beyond self-blame and work toward developing skills that support growth and enhancement.

The feminist therapist recognizes that when problems exist in complex contexts, a client's individual efforts alone will not be sufficient for supporting long-term growth. A client's involvement in group therapy or other self-help options can facilitate the recognition of links between the personal and political by allowing the client to see commonalities as well as differences in the patterns of concerns of group members. In addition, helping clients gain access to community resources that can address additional aspects of their concerns and social contexts (e.g., educational or legal institutions) is important. A willingness on the part of feminist therapists to engage in advocacy on behalf of clients may be crucial to helping individuals access services that can support their empowerment. Thus, investing efforts in the service of social change and social justice is an important extension of the notion that the personal is political. Collective action is often necessary to achieve the social and political change that underpins many stated 'mental' problems.

A second core assumption emphasizes the importance of egalitarianism as a foundation for the psychotherapy relationship and as a goal or outcome of counseling and psychotherapy. The feminist therapist seeks to counteract some of the effects of inequities, oppression, and power abuses present in contemporary society by modeling a relationship based on equality. As such, the feminist therapist works to be transparent, open, and aware of her or his values. Self-knowledge on the part of the therapist helps to ensure that she or he does not inadvertently project biases and stereotypes on the client, which might limit the client's possibilities for growth. The client is seen as the 'best expert' on her or his life, and the ability of the therapist to show respect for the client's expertise contributes to her or his ability to move toward wholeness and health.

To support the value of equality, feminist therapists seek to use straightforward, genuine, and jargon-free language, which then support the client's ability to collaborate in identifying and building on strengths and resilience. Through brief self-disclosure and clear communication, the therapist helps to create a climate that facilitates the client's ability to raise questions and develop skills of assertiveness, which serve as an antidote against disempowerment that she or he may have experienced in the past. The feminist therapist also recognizes that his or her training and expertise make it impossible for the psychotherapy relationship to be fully equal. Discussions between the therapist and client about roles as well as power and knowledge differences within the psychotherapy relationship contribute to the client's ability to deal effectively with power differences beyond the psychotherapy relationship. The goal of equality is also a foundation for informed or empowered consent, which helps to ensure that clients are knowledgeable about the counselor's values and approach to working with individuals, and thus, are able to make clear decisions about whether work with the feminist therapist is likely to be in her or his best interest.

In addition to its importance as a psychotherapy relationship value, and major goal of feminist therapy is to help clients understand power dynamics and power abuses in the real world and to assist them in working toward equality in various spheres of life. Power analysis and gender/social identity analysis, which will be discussed briefly in the section on techniques, become tools for helping clients understand their own positions vis-á-vis sources of power and privilege as well as their experiences of disadvantage or oppression. Feminist psychotherapists assist clients in considering how factors such as race, class, sexual orientation, gender, religion, and other social identities affect their access to power and equality, and work toward helping clients plan how to negotiate equitable and satisfying roles in a wide range of life spheres, such as work, interpersonal, family, educational, and leisure roles. Empowerment is a major component of the goal of equality, and may include self-esteem and self-valuing, positive daily functioning, gender and culture awareness, perceived self-efficacy and control, self-nurturing capacities, problem-solving skills, behavioral flexibility, assertiveness, the ability to access community resources, and participation in social activism (Worell, 2001). Consistent with these core values, research has found that one's self-identification as a feminist psychotherapist predicted greater emphasis on psychotherapy goals related to empowerment and the personal is political (Moradi et al., 2000).

A third major assumption related to feminist therapy is the theme of diversity and intersectionality. Understanding and valuing the diversity of women's and men's lives is central to competent practice. As members of complex multicultural societies, feminist therapists celebrate the myriad interactions among multiple social statuses and categories such as nationality, culture, gender, sexual orientation, race/ethnicity, class, age, and disability. Many social identities (e.g., race, class, gender) and related oppressions (e.g., racism, classism, sexism) operate simultaneously. Although women typically share some common goals and life experiences, gender is only one of many social identities that influence the life course and experiences of empowerment or oppression. Furthermore, gender may seem less salient to some women or men than other markers of identity, privilege, and power, such as race/ethnicity or sexual orientation (Shields, 2008). In general, the complex effects of gender in interaction with other social identities or categories cannot be adequately captured through statistical analysis of interactions. One facet of identity may modify another, making it impossible to tease out the unique effects of gender alone.

The concept of intersectionality reflects the fact that aspects of identity are interrelated and may modify each other or be fused with each other. Thus, for example, gender and race may be inseparable and may be best characterized as gendered racism (Essed, 2001). Alternatively, some aspects of identity may be salient, highly influential, and part of the foreground in some situations (e.g., race or gender), but may be of limited

relevance and only part of the background in other situations. Different social contexts may also elicit an individual's awareness of specific aspects of identity. Thus, an eye to complexity and variability, even when considering the experiences of a single person, is central to competent feminist multicultural practice (APA, 2007).

The Feminist Therapy Institute Code of Ethics (2000) underlines the relevance of diversity to ethical practice, noting that feminist therapists seek to be knowledgeable of their own cultural backgrounds, to broaden their knowledge of cultural diversities, and to monitor their interactions with diverse clientele, being careful to identify and correct personal attitudes and behaviors that may limit their effectiveness.

Feminist Psychotherapy Assessment and Techniques

This section identifies some of the unique techniques and approaches to assessment that characterize feminist therapy. Although feminist therapists rely on many of the tools and techniques associated with other psychotherapies (e.g., cognitive, humanistic, existential, narrative), feminist therapists have developed distinctive methods for helping individuals gain awareness of their multiple identities and place difficulties in context. By placing problems in context, clients are better prepared to direct efforts toward aspects of their lives that they can control or influence and are less likely to internalize negative self-beliefs about areas that they may have limited ability to change, especially in the absence of advocacy and change of institutional structures and cultural attitudes. Tools such as gender and social identity analysis, power analysis, reframing, and strengths analysis are especially important as part of assessment and intervention.

Feminist psychotherapists have been cautious about relying primarily on traditional diagnostic assessments such as the *Diagnostic and Statistical Manual* (American Psychiatric Association, 2013) for a number of reasons, including the fact that traditional diagnostic labels tend to emphasize intrapsychic factors, focus primarily on deficit behaviors, may contribute to the medicalization of problems, and may reinforce subtle gender and other cultural biases. Furthermore, an emphasis on intrapsychic symptoms may contribute to 'pigeonholing' misery rather than contributing to creative methods of addressing pain and supporting growth. Although feminist psychotherapists recognize the value of mainstream labels and assessments (e.g., depression, anxiety disorders) for supporting efficient communication and a common language, they often note the deficiencies of traditional diagnosis for gaining a social-contextual, ecological perspective on problems in living. As a result, gender and social identity analyses have become a hallmark of feminist therapy and facilitate an understanding of how social categories relevant to gender, race, and other social-contextual factors are related to an individual's problems. The assessment of social identities is designed to raise the consciousness of the client about how social roles and categories may be related to his or her current challenges as well as to facilitate collaborative ways of working toward solutions.

Two sets of acronyms are especially useful for organizing social identity and gender role analysis: the ADDRESSING framework (Hays, 2008) and RESPECTFUL assessment (D'Andrea and Daniels, 2001). The acronym ADDRESSING guides exploration of experiences related to age (A), developmental experiences (D), disability/ability (D), religion (R), ethnicity (E), social class (S), sexual orientation (S), indigenous heritage (I), national origin (N), and gender and sex (G). Similarly, the acronym RESPECTFUL can be used to explore religious beliefs (R), ethnic–cultural–racial background (E), sexual orientation and identity (S), psychological mindedness (P), economic and social class factors (E), chronological and developmental patterns (C), threats to health and well-being (T), family history and dynamics (F), unique physical characteristics (U), and location or geographical residence (L). In general, open-ended questions are useful for gathering information about these social categories. Clients are encouraged to reflect on what rules they learned from their cultures about specific identities (e.g., gender-related expectations) and to consider ways in which they experience empowerment, privilege, or disadvantage related to these facets of experience and identity. By clarifying some of the barriers they may encounter, they are able to develop more realistic plans for how to direct their energies.

With regard to the social category of gender, relevant questions may include: What rules did you learn about what it means to be a woman or man? Where and how were these rules conveyed? What are the rewards for abiding by these rules and consequences of breaking rules? How is gender relevant in your work world? What other important aspects of your identity are relevant to the skills you hold and the limitations you experience?

In addition to asking open-ended questions, the therapist may use follow-up prompts that help the client understand or explore biases or privileges and their consequences. To emphasize clients' resilience and strength, it is also useful to inquire about ways in which clients have coped effectively with barriers. Although the acronyms presented above identify potential areas for identity analysis, each therapist develops methods for inquiring about these areas in ways that are natural and integrated with the therapist's style.

Other important feminist therapy techniques include power analysis and strength analysis, including reframing. As a part of power analysis, clients are encouraged to examine the role that power plays in their lives, including power to (personal agency and initiative), power with (collaborative power), and power over (dominance). Key questions include: when and how do clients experience abuses of power, how can abuses of power be challenged, and how can clients learn to experience productive forms of power or empowerment that support positive personal action or collaborative efforts? Strength analysis encompasses any methods for identifying strengths as well as methods for using these strengths in support of health. Reframing, or considering how problem behaviors or situations can be redirected or reconstrued in the service of positive health, is closely related to strength analysis. Strength and coping interventions, which have been components of feminist therapy since its inception, have now been widely adopted by persons who label their work as positive psychology.

Feminist Therapy as an Integrative Approach

Since its earliest days, feminist therapy practice has consisted of integrating feminist philosophical values with a wide variety of techniques that are compatible with a feminist worldview. Any psychotherapy techniques and theories may be integrated with a feminist approach, provided that these techniques do not lend support to biases or outcomes that are inconsistent with egalitarian values. Prior to blending specific psychotherapy approaches with a feminist framework, Worell and Remer (2003) recommended that feminist psychotherapists explore and evaluate specific theories (e.g., humanistic, psychodynamic) by considering the following questions: What forms of bias are embedded in this approach as they pertain to its historical evolution, theoretical concepts, assumptions about the nature of problems, assessment methods, techniques, and the roles of counselor and client? If biases exist, is it possible to restructure aspects of the approach so that it supports egalitarian and social justice goals? How can the approach be enhanced to support individual empowerment as well as social change that will prevent future problems?

The integration of feminist values and other psychotherapy approaches is often seen in approaches directed toward addressing specific issues such as sexual violence, domestic violence, and body image and eating disorders. In these cases, psychoeducation about cultural values such as rape and domestic violence myths or beliefs that support eating disorders is an important component of treatment that enlightens clients about how the personal is political. Through the use of open-ended questions and the discussion of cultural biases, clients are likely to experience greater awareness of their concerns and experience the effects of consciousness raising. A wide range of approaches (e.g., cognitive therapy, interpersonal therapy) can be paired with new awareness of cultural myths and beliefs and used to challenge nonproductive belief systems or develop new coping or behavioral skills. Although outcome research on feminist therapy is limited, it is important to note that the pairing of evidence-based treatments with a feminist worldview provides a solid foundation for competent practice.

Over time, convergence between the goals of feminist therapy and other approaches has occurred. For example, feminist therapies and multicultural therapies increasingly share an emphasis on eradicating injustice. Feminist therapy values related to informed consent (Hare-Mustin et al., 1979) are now widely adopted as important ethical aspects of psychological practice and have evolved as a result of growing understanding of clients as collaborators and shared partners. The impact of feminist values on psychotherapy practice in general can also be seen in APA's (2007) *Guidelines for Psychological Practice With Girls and Women*, which have been adopted as characteristics of optimal practice that transcend specific theoretical approaches. The 11 guidelines are divided into three clusters of (1) diversity, social context, and power; (2) professional responsibility; and (3) practice applications.

The first cluster of guidelines promote an integrated, biopsychosocial, ecological approach to understanding women's lives, and emphasize the importance to addressing socialization, multiple and intersecting identities, and experiences of privilege and disadvantage or oppression. The guidelines also encourage psychologists to be aware of ways in which biases can be institutionalized in health systems, education, the workplace, religious groups, legal systems, and family systems. By being mindful of these biases, psychologists are able to help clients separate internal from external causes of distress and to resist confining cultural socialization. In addition, psychologists are encouraged to integrate community resources with their psychotherapy work and to emphasize prevention and resilience (APA, 2007; Enns et al., 2015).

The second cluster of guidelines, which focus on professional responsibility, advises practitioners to be aware of the strengths and limitations of traditional diagnoses, assessment processes, and interventions. These guidelines encourage psychologists to implement methods that build on client strengths and that challenge barriers to wholeness. The benefit of inclusive, flexible definitions of mental health and goals is highlighted, as are recommendations that contextual and cultural aspects of people's lives receive emphasis. The importance of therapist self-awareness and self-monitoring is also identified as a major feature of professional responsibility (APA, 2007; Enns et al., 2015).

The third and final cluster speaks to specific interventions. Practitioners are encouraged to use approaches that support collaborative, power sharing relationships, and empowerment and client initiative. Practitioners are advised to recognize that optimal growth is likely to be enhanced through the use of community resources, educational services and centers, shelters and safe houses, work resources, and public assistance, and to draw on these resources to expand services available to clients. Finally, the importance of devoting attention to changing systemic and institutional biases is discussed. Practitioners are encouraged to extend the purview of their work to include social justice, advocacy, and public policy initiatives (APA, 2007; Enns et al., 2015).

Conclusion and Future Directions

The initial focus of feminist therapy was to name biases and to create a validated discipline to address them. Consciousness raising groups increased personal insights, which led to the use of these methods in feminist psychotherapy practice. Over time, feminists have examined ways in which early 'grand theories' of feminism are limited for understanding the complexity and diversity of individual lives, especially when considered in transnational context. Feminist psychotherapies based on 'locational' feminisms are emerging in multiple regions of the world (Enns, 2004, 2012; Enns et al., 2015), and are incorporating culture-specific practices and knowledge. Feminist multicultural and transnational psychotherapies are likely two major areas of growth during the twenty-first century.

Feminist Research and Social Work

Abstract

Growing from challenges to dominant, masculine thinking and action for social change for women, feminism offered frameworks for practice and research. Social work's unique relationship to women as the majority of its workforce and as clients fits well with evolutions in feminist thought. Key debates within feminism are echoed in debates within social work, including challenges to traditional research modalities, views of the domestic sphere, conceptualisations of ethics and ideas of the self-aware researcher. This article provides an overview of what feminist social work research is, how it is informed by feminist theories and research methodologies.

Introduction

The nature of social work as both a profession of mostly women and as a profession that works with mostly women means that it is a practice and scholarly discipline that has been strongly influenced by the women's movement and feminism. As prominent feminist social work researcher Lena Dominelli observed, arguments about the purpose of social work are bound up with debates about women's position in the social order, thus feminist debates have conceptual frameworks that respond to and fit with 'the changing nature of women's lives' (Dominelli, 2002). Sands and Nuccio (1992) also observed that many social work researchers have found a high level of compatibility between feminist theories and social work. Supporting this, is a detailed meta-analysis of empirical studies on the effectiveness of feminist social work practice methods by Gorey et al. (2008) who found that feminist interventions were more effective than those based on other practice methods.

However, social work research has been historically dominated by nonfeminist research and debates have been sustained around the application of experimental/empirical and nonexperimental approaches with no reference to gender relations (Gibbs, 2001; Trinder, 2000: p. 10). More recently, the focus of social work research has shifted from national, large-scale surveys on the "structural determinants of needs and problems to a narrower focus on the effectiveness of different interventions; an analysis of the dynamics and meanings in relationships; and a developing research agenda of the politics of identity and individual agency" (Gibbs, 2001: p. 691). Critical or standpoint feminist research has been historically dominant in feminist social work research, drawing its theoretical principles primarily from Marxism and radical feminism (Trinder, 2000: p. 44; Swigonski, 1994: p. 391). However, since the early 1980s, there has been a strong trend toward postmodern/poststucturalist feminist research (Trinder, 2000; Fawcett et al., 2000; Sands and Nuccio, 1992). This shift in methodology has been highly influenced by key feminist thinkers such as Judith Butler (1990), who posed many theoretical challenges related to feminist advocacy, the construction of gender and meaning, and language and ideas within feminist research. The postmodern turn has been influential across all social work research as the desire to see research participants as having fluid identities and being active agents, not only to understand, but also to empower participants in the research process, has become part and parcel of more self-reflective social work theory and practice. Williams (1996) argued, however, that feminism as a broad modernist epistemology had already done much of the work of postmodernism in that it provided a critique of universalist thought that had been wholly focused on male thinkers taking a male-centered view. This challenged the binary view of male/female by calling for equality; the private/public divide by making both spheres political; becoming suspicious of 'meta-narrative' by listening to women's voices and their experiences of power; and showing the power of the ideological representation of women as whores or mothers (Williams, 1996: pp. 64–65).

Broadly, feminist theory both motivates research and provides incentives for doing research, as well as integrating the relationship between activism, advocacy, research, and social change. This can be seen most clearly in relation to key social work fields such as child sexual abuse and domestic violence. Through consciousness raising and solidarity, women's liberation movements from the late 1960s to the late 1980s opened up spaces for women to speak of their experiences of violence and sexual abuse previously hidden in the private sphere of the home and to demand that previously unspoken and hidden abuses of gendered power were placed on governments' social policy and legislative agendas (Dominelli, 2002: p. 37). Feminist research has played a key role in bringing about reforms for appropriate responses to and training for authorities such as the police, the courts, and medical professionals.

Since the early 1990s, feminism in general has battled to maintain a public discourse that recognizes gender inequalities in both private and public spheres in Western countries where neoliberal agendas focusing on markets over social objectives have dominated politics (Hannam, 2007: p. 161). However, this has not occurred internationally where human rights and development policies have increasingly taken account of and included feminist objectives for social change (Lazzari et al., 2009: p. 348). Nevertheless, feminism has had a profound influence on social work practice, theory, and research (Fawcett et al., 2000). Like feminism, social work is far from homogenous and approaches to social work research reflect a wide range of disciplines and epistemologies. Feminist social

work research, while working within specific disciplines such as sociology, political science, ethnography, or psychology, shares the wider task of feminism, which seeks to transform traditions within disciplines to create an intellectual revolution that contribute to broad social change objectives (De Vault, 1990).

Feminist social work research is conducted across all fields of social work practice as well as in teaching and learning and theory building. Prominent fields of feminist social work research are where feminists have had a groundbreaking influence in social and political responses to social problems. For example, research on violence against women has resulted in significant changes within legal, policy, and practice responses (Laing et al., 2013). The field of care has also been heavily researched and influenced by feminist social work researchers. This arose from feminist demands, on the state and society, to recognize the value of care work and women's dominant role in caring for children, people with disabilities, and older persons and to fundamentally challenge the ethics of care. Other roles in society dominated by women are also of great interest to feminist social work researchers, such as poverty, child abuse, volunteering, community work/development, international development, sexual assault services, aging, youth services, and mental and wider health services (Kurz et al., 2005; Kisor and Kendal-Wilson, 2002; Featherstone, 2006; Hanisch and Moulding, 2011).

Feminist Research: Objectives and Methods

Following the development of the women's movement across the world during the 1960s and 1970s, the scholarly framing of specifically identifiable feminist research methodology and research objectives emerged during the early 1980s to the 1990s (Eichler, 1987; De Vault, 1990; Wolf, 1996; Reinharz, 1992). Feminist research has since adhered to specific ways of researching that have supported the objectives of the women's movement and scholarly feminism in its ever-transforming manifestations. Feminist research has been characteristically concerned with the oppression and exclusion of women; identity and difference; the value of subjectivity and personal experience; setting itself apart from reductionist scientific research; women's ways of knowing; and listening to and hearing women's voices.

Reinharz (1992) viewed feminist research as methods used in research by self-identified feminists; as research published in feminist journals; and as research methods externally recognized as feminist research. This may exclude feminist researchers who approach their research with a feminist agenda, but do not necessarily identify as feminist (Dankoski, 2000: p. 7). Reflecting a postmodern framework, Lather (1988) suggested that feminist research puts the social construction of gender at the center of research inquiry. A further differentiating feature of feminist research is that it 'moves the researcher into the role of change agent,' using research findings 'to influence or change the lives of those studied and of other members of the group' (Cummerton, 1986: p. 95). Harding argues that the focus of feminist research is not on methods, but on the way feminists do research. She observed that they "listen carefully to how women informants think about their lives and men's lives, and critically to how traditional social scientists conceptualize women's and men's lives' and tend to focus on activities previously thought of as insignificant" (1987: p. 2).

Due to the diverse epistemological differences in feminist research, it is impossible to propose a singular definition. However, feminist researchers are primarily concerned with understanding why inequality between men and women exists and why there is the overall domination of men over women. The point on which the different feminist approaches disagree, however, is about where to find the answers to these questions and how to proceed in transforming women's lives through liberation from oppressions and inequalities (Letherby, 2003).

The pluralisms of feminisms are politically important to feminist researchers as they challenge a singular, universal feminism or feminist approach as an essential aspect of contemporary feminist thought. The various strands of feminism include liberal, radical, lesbian, liberationist, Marxist, socialist, ecofeminist, standpoint, third world, postcolonial, poststructuralist, and postmodern (Hannam, 2007; Reinharz, 1992: p. 6). These theories or political identities are often associated with a struggle between the structuralist and poststructuralist or modernist and postmodernist-based feminisms, reflecting the persistently, debated nature of feminist thought and practice. Broadly, the key difference between modernist feminist theory and postmodernist feminist theory is around how to explore the ways women exist or are placed in relation to men.

For structuralist feminists, the solutions are in targeting the structures that oppress women and maintain their inequality, from the interpersonal to the broad structure of the patriarchal state and the law. Therefore, structuralist feminists seek to establish universal truths about women's oppression. For poststructuralist feminists, the struggle is over meaning and the power of meaning that is primarily conveyed through language or discourse and is based on the fluid concept that there is no single truth or generalizable experience of being a woman. Therefore, the strategic approach to change is in the theorization and critique of discourse, knowledge, truth, reality, rationality, and the idea of the socially constructed subject (Sands and Nuccio, 1992). This approach has led to the primacy of individual narratives in social work practice and research, which in turn, has raised concerns for structuralist feminists because it ignores collective communities that are so integral to many women's lives (Dominelli, 2002: p. 35).

Despite these debates, and the generalized trend to frame feminism within the more general terms of gender, gender equality, and gendered society, rather than a focus on women per se, key feminist concerns persist. Such concerns are at the core of feminist social work research and are based on ways of understanding broader social injustices and inequalities between men and women by taking a women-centered or gender-aware approach. This includes a strong adherence to taking into account key intersections of difference such as class, disability, ethnicity, race, sexual preference, or religion.

Feminist Social Work Research Methodologies

Feminist social work researchers involved in knowledge production and aiming to make a difference to women's lives,

utilize a wide range of research methods, including qualitative and quantitative approaches. Within these broad approaches, there are defined feminist methodologies of research and knowledge production. Feminist researchers approach research from a political perspective that acknowledges inequalities between men and women and that traditionally the research process has been exploitative and hierarchical (Letherby, 2003; Reinharz, 1992). Feminist methodologies are informed by the drive to address women's position in society and ensure that the research process is transformed so as not to repeat wider oppressions that women experience. This includes methodologies such as feminist informed interview practice, which draws on a body of feminist ethics that deliberately separates itself from the scientific ethic of a 'detached' and powerful differentiation between the researcher and the subject. This approach is to counter the historical experience of women's voices and experiences being excluded from research as well as traditional scientific exploitation of subjects in the research process, and forms the epistemological basis of feminist social work research (Letherby, 2003).

Standpoint feminist social work research commonly applies qualitative methods, but also utilizes a quantitative approach that intrinsically seeks a collaborative position between the researcher and the research participants. Originally drawing from Marxism, standpoint feminism sought to uncover and challenge women's oppression, but transformed to take account of difference, reflecting an epistemological break from modernism (Heckman, 1997: pp. 356, 362). In standpoint feminist theory, the original tension between social construction and universal truth was challenged by deconstructing it and conceiving of knowledge as situational and part of a discursive process (Heckman, 1997: pp. 356–357). It represents the early dominant structuralist or modernist feminist as well as more recent postmodernist approaches in social work research, particularly in the field of domestic violence.

Also reflecting the influence of the postmodern turn is an increasing application of 'intersectionality' as an analytical tool that is concerned with the intersection between race, gender, and class, and allows for a focus on the relevance of inequalities and differences between and within social or economic groups (Jordan-Zachery, 2007). Although many authors credit Kimberlé Crenshaw (1989) with originating 'intersectionality' for feminist research, Butler's critique of the universalized term women/woman as a fixed identity also gave rise to the idea of intersectional approaches, when she observed that

> …the term fails to be exhaustive, not because a pregendered "person" transcends the specific paraphernalia of its gender, but because gender is not always constituted coherently or consistently in different historical contexts and because gender intersects with racial, class, ethnic, sexual, and regional modalities of discursively constituted identities. (1990: p. 4)

Butler is critical of intersectional feminist methodology because it presents a list of fixed identities, emphasized by the often added 'etc.' (Butler, 1990: p. 143). Intersectionality is utilized by both structuralist and poststucturalist feminists because it addresses 'the most central theoretical and normative concern within feminist scholarship,' that of the recognition and acknowledgment of differences among women (Davis, 2008: p. 70) thus addressing the major critique of dominant early structural feminism's exclusions of certain groups of women through the universalization of the category of women.

Mehrotra made the observation that "as an eclectic, evolving body of scholarship that is committed to social justice and the empowerment of all women in diverse communities, feminist social work is well-positioned to engage with questions regarding intersectionality theorizing and its relevance to social work scholarship and practice" (2010: p. 418). Mehrotra (2010) highlighted four key characteristics of intersectional analysis: placing the lived experience of people of color and other marginalized groups as central to development theory; revealing how diversity within groups is often ignored and essentialized while exploring complexities of identity within groups; showing how social inequality and oppression are manifested in domains of power; and promoting social justice and social change through the research process.

Further to the broad methodological approach of intersectionality, there are specific feminist research theorizations about the positioning of the researcher as self-aware and self-reflective. For example, Mehrotra describes herself a 'South Asian queer woman' who focuses her research on lesbian, gay, bisexual, transgender, and queer communities of color and South Asian migrant communities, thus demonstrating the relationship between the researcher and the research subjects and the lived experience of intersectionality' (2010: p. 418). This is connected to the core radical feminist theory of the personal as political and is manifested in research processes. However, it is also an approach shared by postmodern feminist researchers who adopt a view that their experiences will inevitably affect the research and cannot be seen as separate from the data derived from the research (Wendt and Boylan, 2008: p. 602). This approach draws largely on the highly influential theorization of reflexivity in practice by Jan Fook, who defines reflexivity as the process of being able to locate oneself in the context of work or research and appreciate how one affects or influences the research or practice through one's own beliefs and perspectives and social, economic, and political background (2002: pp. 157–158). Importantly, these components of the self-reflective researcher are related to understanding the exercise of power through knowledge and discourse.

For international research that takes place in the Global South and is conducted by feminist researchers from rich nations, similar concerns arise in fieldwork. Feminist theoretical approaches provide guidance on how to conduct research in this context that is sensitive to power imbalances and does not repeat the errors of previous exploitative scientific approaches that resulted in a form of colonization or recolonization (Wolf, 1996). Postcolonial feminist research methodology specifically addresses the issues of power and inequality between researcher and research participant by prioritizing, regardless of their economic or social position, that women's voices should be heard in research and that it is a key task of the researcher to facilitate listening to their voices.

Contemporary feminist social work research is disseminated widely through key international and national refereed journals. For example, *Affilia: A Journal of Women and Social Work* is a prominent, dedicated feminist social work journal publishing peer-reviewed research papers since 1986. Other leading social work journals are important vehicles for the dissemination of feminist social work research, such as the *British Journal of Social Work*, *International Social Work*, and *Australian Social Work*.

Despite its presence in prominent journals, there is also research about the lack of representation of feminist research, and feminist consciousness in wider published social work research, compared to the presence of feminist social work practice. For example, Barretti (2011) conducted a content analysis of abstracts of 17 United States–based social work journals over two 10-year periods up to 1996 and then up to 2007, and found a decrease in the latter period in both 'women's' and feminist content, suggesting that the strength of the relationship between feminist research and social work research had diminished in that time. A search in 2012 of the US National Association of Social Work's journal *Social Work Research*, published since 1995, showed a low presence of feminist social work research. The number of papers that included the words 'women' and/or 'feminist' in the main text was 268 over a 17-year period, a relatively low representation compared with 2168 in the comparable *British Journal of Social Work* over the same period, perhaps indicating a stronger presence of feminism in British social work research than in the United States. Barretti noted that the presence of the designated feminist social work research journal *Affilia* in the United States, which has also seen a decrease (by 24%) in its articles informed by feminism, adds to the sense that women's content across social work research in general can be supplemental, and seems to be suffering retrenchment (2011: p. 275). Feminist researchers and others, who have taken up issues raised by feminists, have also turned the research lens on social work journals and wider research to demonstrate not only the absence of feminist research but inherent sexism within the published research and tendencies to ignore the implications of gendered social issues in practice (Pease, 2011: pp. 408–410; Parton, 2003: pp. 10–11; Dietz, 2000).

The Focus and Future of Feminist Social Work Research

Feminist social work research is pervasive across all human service and social policy areas. However, there are some areas of social work research in which feminist researchers are more evident or visible than others (such as domestic violence, family support, child protection, childcare, and 'care'), often due to the high presence of women as clients in key areas of social work practice. It is also the nature of social work that it overlaps with other professional domains and scholarly disciplines. For example, in health and mental health, feminist social work practitioners and researchers play significant roles, but in such a huge field, they are often overshadowed by the dominance of biomedical practice and research, or other 'care' professions. Just three core areas are discussed below.

Aging

Social work with older people is an area of rapid growth due to worldwide population aging and consequent demands for greater research. This is particularly important for feminist research, as women constitute a dominant group among elders within most communities and the majority of older women have lived unequal lives due to their gender and caring responsibilities and their experiences have been largely ignored in mainstream research (Bozalek and Hoolyman, 2013). Feminist social work research has focused on older women and homelessness; abuse and exploitation of older women; caring roles of older women; intersections of race, sexual orientation, human immunodeficiency virus infection/acquired immunodeficiency syndrome, gender, age and class; effects of work and retirement; older women and autonomy and agency; and older women and welfare (Browne, 1995; Bayliss, 2000; Langley, 2001).

For feminist social work researchers, there are not only previously neglected areas of research on aging and the needs of older women, but also an impetus to apply the range of feminist approaches to lift knowledge and social work responses to the needs of older women to achieve emancipatory change. An example is Patterson's (2003) feminist study exploring the life courses of 25 Asian and Caribbean born elderly women who migrated as adults to the United States, which directly links its findings to improve social work practice with diverse older women from diverse backgrounds. The study emphasized the 'participant as expert' in their own lives approach and the potential for such documented experience to teach effective and appropriate social policy and social work practice.

Future feminist social work research on aging will continue to resist the dominance of biomedical knowledge production about aging; to reveal the complexity of women's life narratives to combat ageist and stereotypical ideas of women's histories; to explore the impact of menopause, equal to fertility and reproduction; to reveal distinct experiences of older women's poverty and secondary economic status; to establish knowledge of strengths in women's aging and counter marginalization of older women; and to do research that integrates developments into wider social justice issues linked to the diverse places and roles of older women.

Domestic Violence

Findings in early feminist research on domestic violence had a profound impact on how social workers responded to women as victims of violence. A study by Dobash and Dobash (1979) found that in the United Kingdom, police, court personnel, and other helping professions functioned as obstacles to the safety of women suffering domestic violence, establishing that social worker responses lacked resources and reflected beliefs that the violence was the woman's problem and that the social worker's role was to maintain the nuclear family structure. Equally significant was the research by Stark and Flitcraft (1996) that revealed the extent of domestic violence through the rate of injuries of women presenting to hospitals and established that feminist advocacy and safe refuge are a key elements of women's safety from domestic violence. This kind of research was crucial for naming

the issue of domestic violence and developing a research practice that began to listen to women's voices about their experiences of violence.

The focus of feminist social work research has been on establishing the complexity of violence perpetrated by intimate partners, to include emotional, financial, and physical dimensions; assessing the extent, cost, and impact of domestic violence across diverse communities; establishing links between domestic violence and risks for children; mental health issues for women arising from experiences of domestic violence; the relationships between housing, homelessness, and domestic violence; the impact of sexual orientation, social, and cultural roots of violence against women; lesbian experiences of intimate partner violence; and legal issues and deaths related to women's protection and security after leaving a violent relationship. An example of effective feminist research in this field is a study by Laing et al. (2012) that draws on a large research enquiry of four separate studies that explored collaboration between mental health and women's domestic violence services and resulted in enhanced collaboration across the domestic violence and mental health sectors, resulting in important benefits for women dealing with domestic violence and mental health issues.

International studies on domestic violence represent the scope of intersectional feminist social work research (Sokoloff and Pratt, 2005). It also shows a lack of progress by governments in responding to domestic violence in many countries and that civil society organizations are most active in achieving gains in social policy responses (Htun and Weldon, 2012). The future will see a growth in international feminist social work research on domestic violence as social work research catches up with activist feminist advocates working in the civil society sector. Analyses of key global social policy responses to violence against women, indigenous peoples' demands for survival and gender equality, and critiques of policies such as the United Nations Millennium Development Goals (MDGs), which have done little to improve women's equality status globally, will become an increasing focus. Dominelli (2010) also points to wider concerns for social work in the global context in noting that the MDGs are unlikely to meet their goals, including challenges brought about through financial pressures such as the global financial crisis and environmental or ecological crises due to climate change and industrial globalization. These issues, plus a need for 'green social work,' are part of the future social work research agenda (Dominelli, 2010, 2012).

Care

Although early feminist engagements with the notion of care were primarily concerned with the critique of care as gendered labor, more recent conceptualizations have valorized women's capacity and resourcefulness in caring activities. Feminist social work research into 'care' has been conducted within the range of practices and policies that inform its broad conceptualization. This includes a theoretically postmodern, emancipatory shift for the 'cared for' in the idea that care should no longer be viewed as a one-way process of dependency, as many studies have revealed that there is a higher level of mutual benefit in care relationships and that often the person constructed as the cared for also cares for their carer (Tronto, 1993; Berridge, 2012). Within social work, care encompasses the care of children, within families, fostering and communities and by the state as well as private and institutional care for children or adults with disabilities and care for frail-aged people. A major early focus for feminism was the taken for granted status of gendered nature of care, particularly a mother's care for children. More recently, focus has been on the fact that it is commonly a woman's role to care for disabled family members of all ages, elders, and grandchildren. Feminist research in care also engages with the status of the cared for, particularly in the area of aging as women's longevity has led to a higher demand for the care of frail aged women.

As a core challenge to the traditional philosophy of ethics and to engage with the gendered nature of care, and reform of how care is conceived and emphasize its societal contribution as a service, feminists have developed a feminist ethics of care (Parton, 2003; Sevenhuijsen, 1998). Like all areas of feminist thought, there is not a single set of ethics of care; however, there are key principles. The first articulations of feminist ethics were in countering classical liberal theories of the isolated individual and women taking responsibility for others as a form of moral strength and social interconnectedness (Gilligan, 1982: p. 17). Thus, "the moral subject in the discourse of care always already lives in a network of relationships, in which s/he has to find balances between different forms of responsibility" (Sevenhuijsen, 2000: p. 10). Carol Gilligan described a structuralist positioning for a feminist ethics of care as an "ethic of resistance to the injustices inherent in patriarchy … where it transcends gender binaries and hierarchies that structure patriarchal institutions and cultures" (Ethics of Care, 2011: p. 1).

Further developments in the feminist ethics of care saw an emphasis on relationships over rules and rights, as care was recognized as intrinsically bound to social practices, feelings, and opinions, and seen as a moral activity rather than a gendered one, therefore determined as a woman's role (Tronto, 1993). Feminist social work research took the framework of the ethics of care into all spheres of care research, including social policy analyses; the positioning of mothers in families where children have been sexually abused, child welfare and child protection; care and carers of people with disabilities; women's labor in the care industry; international perspectives on women as carers; and the experience of being a carer (Featherstone, 2006; Hanisch et al., 2011; Parton, 2003). An example of the latter research is Anne Petrovich's studied account of becoming a 'sandwich carer,' where she explores complex demands of working in the paid workforce, care as a mother; care as daughter of frail aged parents; and care and death, raising key issues related to self-determination, responsibility, and the complexity of care relationships (Petrovich, 2008).

Conclusion

For feminist social work research to maintain its momentum for social change that includes progress toward consistent, shared gender equality, it appears that a reaffirmation of the

role of feminist social work theory and research is required. Feminist methodologies that are currently applied have overlapping characteristics that reflect the evolution of feminisms more broadly. Regardless of epistemological identity, feminist research in social work has moved beyond failures of early Western feminism to recognize diversity and difference in the experiences of being a woman or women and has transformed the way that research is done by actively resisting the normative scientific approach that historically ignored the voices of women. It also refused to subject research participants to strict hierarchies encompassed by the professional researcher being the subject while the participant was the object of the research. Diversity across a range of social, cultural, and economic divisions is also a key theme within the practice of feminist social work research as its web of engagement extends to all areas of human services and social issues and contributes to change in social work and social policy practice and theorization.

Despite a general disquiet that feminism had stalled in the West, debates about feminist approaches to social work research continue to be present in social work education and, there appears to be an ongoing commitment by educators to ensure that feminist approaches are not lost and remain diverse. Further, the increasing internationalization of feminist research due to rapid changes in the populations with whom social workers work with across the world, related to growth in the number of refugees and rapid changes in immigration, poses fresh demands for increased expansion of feminist social work research (Kreitzer, 2002; Erez et al., 2009).

Feminist Theory: Radical Lesbian

Wendy L Lee, Bloomsburg University of Pennsylvania, Bloomsburg, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Reworked via socialist feminist and ecologically motivated objectives, radical lesbian feminism offers a powerful theoretical, practical, and morally sound framework for the contemporary ecofeminist movement. First, by appealing to the strengths of earlier analyses, radical lesbian feminism offers a critique of compulsory heterosexuality. Second, what distinguishes radical lesbian feminism from liberal feminism is the former's commitment to reclaim women's experiences, desires, bodies, and lives as meaningful in themselves. An ecologically oriented radical lesbian feminism offers an avenue for comprehending that experience informed, for example, by the ever-growing threat posed by climate change. Lastly, the emancipation of lesbian identities is essentially revolutionary in that it aims to undermine institutions responsible for oppression. Such a revolution has a specifically ecological signature in that the most globally threatening configuration of oppression to date – oppression premised on access to drinkable water and breathable air – is itself the product of heteropatriarchally dominated multinational energy corporations.

Introduction: Three Vital Foci of Radical Lesbian Feminism for a Twenty-First Century World

While some might insist that the heyday of radical lesbian feminism concluded with the end of the twentieth century, in what follows I'll argue that, suitably reconfigured via socialist feminist and ecologically motivated objectives, radical lesbian feminism offers among the most powerful theoretical, practical, and morally sound frameworks for the contemporary ecofeminist movement. Three objectives or foci will govern my argument: first, appealing to the strengths of earlier analyses, radical lesbian feminists offer what remains the 'gold standard' critique of compulsory heterosexuality that defines male sexual access to women's bodies as 'natural,' thus institutionalizing male sexual and economic entitlement. Such analysis, I'll argue, remains vital to contemporary theorizing and activism because it demonstrates in what heteropatriarchal prerogative consists and how it dominates institutions and practices affecting women's lives, particularly with respect to essential resources like drinkable water and breathable air.

Second, what distinguishes radical lesbian feminism from liberal feminism is the former's commitment to reclaim women's experiences, desires, bodies, and lives as meaningful in themselves. As opposed to the more or less unquestioning adoption of male-defined values by liberal feminism, radical lesbian feminism interrogates whether, for example, aspiring to become the first female chief executive officer of Dutch Royal Shell is a goal worth pursuing. Radical lesbian feminism also takes women's particular experiences – as mothers, daughters, wives, and as lesbians – not merely as defined in connection to male counterparts, but as culturally, geographically, religiously, and sexually specific. An ecologically oriented radical lesbian feminism offers a new avenue for comprehending women's experience as informed by the ever-growing threat from extreme forms of, among other things, fossil fuel extraction. Both inside women's bodies in the form of carcinogens like benzene associated with breast cancer (one of the multitude of additives to drilling fluids and hence to waste water), and with respect to responsibilities traditionally shouldered by women especially in the 'developing' world, such as the increasing scarcity of fresh water, women's experience of the heteropatriarchal domination of energy production and usage informs not only theorizing about women's experience of deforestation, desertification, pollution, and ultimately climate change, but also for strategizing an activism aimed at emancipating women, children, and indigenous peoples from this domination. Because radical lesbian feminism makes women's experience central to its philosophical framework, it is in a position to provide a powerful voice to those impacted by the multinational corporatism of industrial-level fossil fuel extraction.

Third, I'll argue that the aims of radical lesbian feminists include at least the subversion of heteropatriarchal institutions or – better – their end in that such institutions either require the denial of lesbian identity or insist on defining it in terms of male desire and privilege (such as male-focused female-on-female pornography). In other words, insofar as 'lesbian' does not exist for a sexuality defined in terms of male access to women's bodies, radical lesbian feminists have sought to redefine and radicalize 'sexual identity' to not merely include 'lesbian,' but to deepen and broaden sexual identity well beyond notions of male pleasure or male access. As a forceful expression of the feminist slogan 'the personal is political,' radical lesbian feminists seek the emancipation of lesbian identities as part and parcel of the emancipation of sexual and/or gender identities themselves. Such emancipation is, in fact, a revolutionary reach beyond sexual and/or gender expression: the emancipation of lesbian identities just is a revolution that aims to undermine institutions responsible for oppression. Such a revolution, moreover, has a specifically ecological signature in that the most globally threatening configuration of oppression to date, namely, oppression premised on access to the necessary conditions of life – drinkable water and breathable air – is itself the product of heteropatriarchally dominated multinational energy corporations.

In light, then, of its critique of compulsory heterosexuality, its focus and revaluation of women's experience, and its revolutionary understanding of sexuality and gender expression, radical lesbian feminism offers, I'll argue, a theoretical framework for an ecologically oriented feminism aimed at substantive social, economic, and environmentally effective change.

The Radical Feminist Lesbian Future

Emerging from mainstream liberal feminism of the late 1960s and early 1970s, radical feminists challenge the prevailing view that liberating women consists in reforming social institutions such as marriage, family, or the organization of work. They argued that insofar as a deeper analysis of these institutions demonstrates the extent to which some men (white, Western, middle-class, and mostly Christian) continue to be privileged over other men and virtually all women, reform alone cannot achieve the equality liberal feminists envision. Economic equality in a world whose prevailing values and institutionalized practices systematically empower some at the expense and exploitation of those defined as other, inferior, or marginalized can never be more than cosmetic. Radical feminists thus promote not reform but revolutionary change in the ways the deeper and more endemic inequality conceive gender, sexual identity, and sexuality. The aim is to end the oppression of women by creating first awareness and then resistance not only to male-dominated or patriarchal institutions, but also to the conceptual frameworks that sustain them.

Since that time – some 30–40 years later – much has changed for both lesbian feminists, and for radical lesbian feminists. Indeed, the feminist movement has become both more revolutionary in some important ways and less so in others. While, for example, the critique of heteropatriarchal institutions has been embraced by many feminist theorists and activists, those same institutions, particularly at the level of military, corporate, and government hegemony, continue to expand in ways that reaffirm and empower some men. To take one striking instance, the global fossil fuel industry has come to epitomize the domination of white, affluent, mostly men over existential necessities such as water. In the face of climate change, combined with the fact that women – particularly in the developing world – remain primarily responsible for tasks that require clean water, such domination could effectively undermine many of the gains made over the twentieth century not only by women, but also by developing world peoples.

Climate change, in other words, functions as an effective barometer of the success of twentieth century social movements – including the radical feminist movement – in that the same institutions responsible for the production and emission of potentially catastrophic quantities of greenhouse gases – military, government, and corporatist – are also responsible for the ongoing oppression of women, children, indigenous peoples, and the economically marginalized. Hence, analyses of the causal, political, and economic conditions responsible for climate change are crucial to any twenty-first century analyses of marriage, work, and family. As many socialist feminists point out, these are precisely the institutions at once reinscribed as units of economic reproduction by global corporatism and profoundly threatened in their capacity to reproduce labor and laborers as access to clean water becomes increasingly scarce. Indeed, it adds another layer of meaning to show that institutions that have functioned as sites of oppression for women, marriage, for example, also support – quite literally – the manufacture of global and potentially ecologically catastrophic conditions. Because radical lesbian feminists offer some of the most trenchant analyses of the concepts sustaining this heteropatriarchal 'Old Boys Club,' they are arguably in the best position to expand analyses to incorporate more explicitly environmentally oriented strategies of resistance.

If any single motif governs feminism as a whole and its specific domains of theory and practice, it is the necessity to expand beyond the issues governing the movement's third wave – including matters of sexual identity, expression, and politics. This is not to say that such sexual issues have become less important. Quite to the contrary, it is to say that twenty-first century feminist analyses must take into consideration subject matter not explicitly thematized in earlier incarnations of the movement, but that affects how its central themes are understood in the face of new challenges – especially environmental challenges that affect the quality of human life, and the mobility of human populations. To take one example, the endocrine system disruptions to which we are exposed in so-called feminized fish, solicit a set of contentious questions concerning not merely why we continue to use this terminology, but why it continues to resonate with us epistemically. That we all know to what such terms refer implies precisely that fixed set of characteristics are identified as 'feminine' or 'masculine,' and thus offers a radical lesbian critique a potentially fruitful new context toward offering more acute analyses of a language use that reinforces oppressive conceptions of gender.

To take a different kind of example, consider the ways in which transexuality has come to challenge the ways in which we conceive 'nature.' When the 'natural' can become the end result of highly specific, technologically mediated, intervention, the word 'nature' arguably forfeits the meaning 'original' or 'real.' But this contentious use of 'nature' has a potent analogue in contemporary environmental discourse over whether, for instance, ecological 'restoration' can restore an ecosystem to its 'natural' – original – state, or whether such interventions on damaged or destroyed ecologies amount to no more than cosmetic change. The transsexual may believe that he or she is realizing – potentially even restoring – the sexual and/or gender identity he or she was 'meant' to have. The restoration ecologist hopes their work restores an ecology to an original 'as it was meant to be' state. But given the technologically mediated nature of both appeals to 'nature,' it is a murky business what 'nature' could usefully mean. Such, however, are precisely the questions to which radical lesbian feminists have offered acute attention since the 'natural' and the 'unnatural' function as conceptual as well as political, social, and economic sites of oppression in virtue of sexual and/or gender identity.

The Critique of Liberal Feminism

Perhaps what most obviously differentiates mainstream liberal feminism from its radicalized sister is that while the former continues to hope that the master's tools (e.g., capitalism, extractive technologies) can be deployed to dismantle and then rebuild a better version of the master's house (e.g., economy, environment), the latter has largely quit this project of rebuilding and jettisoned its tools in favor of building not merely a house but an entire conceptual 'civilization' whose collective mission it is to embody the experiences, values, and desires of women. That the master's tools cannot be deployed

to dismantle his house could not be made clearer than by climate change; for whatever relative equality some women have gained, there is little reason to believe women's emancipation has contributed to slowing the demand for fossil fuel extraction, preventing deforestation, or dealing effectively with water and air pollution. In fact, the opposite is likely to be true; in the absence of any sustained critique of the competitive and avaricious tools of heteropatriarchal institutions, there are no good reasons to think women will behave in any more environmentally conscious a way than men. Climate change is simply evidence to that end.

If what we mean by 'radical' directs us to analyses of the tools – the concepts – out of which the master's house is built, radical lesbian feminists are especially well positioned; as Audra Lorde put it, the master's tools cannot be used to dismantle the master's house. By refusing such tools in favor of those that probe first and foremost what the master's tools are for, radical feminists may occupy the best position to see that the master's house is merely the 'McMansion' whose supersized energy consumption epitomizes the use of a 'tool set' that, while it can accommodate a few tokenized women, can be put to building only one kind of house – the house that reaffirms the master. In other words, while the primary focus of liberal feminism has been the evaluation of patriarchal institutions in the interest of retooling them to affect greater inclusion for women within them, radical lesbian feminism takes its point of departure from the observation that tools used for the purposes of exploitation and oppression may not be suitable for emancipation or, as we now see, the construction of a sustainable future.

Perhaps, however, the fundamental insight for contemporary radical lesbian feminism was the recognition that it could never be enough to agitate for inclusion as long as women's value is based on men's interests and desires. This too comes into sharp focus via the facts of climate change. The merely cosmetic improvements for women produced through liberal feminism's focus on reconfiguring the master's tools fails to address very real-life and death issues – the having and rearing of children, for example – under conditions that expose mother and child to environmental toxins, scarce clean water, and potential mass migrations from shrinking coastlines. In this light, liberal feminism must be understood not simply as cosmetic but as complicitous in the oppression of women and compromised others while more privileged women enjoy the fruits of that exploitation of labor and resources. What radical lesbian feminists insist is that the change necessary to produce lasting improvement in all women's lives – including the effort to mitigate climate change – requires understanding how heteropatriarchal institutions are not merely oppressive, but threaten the conditions of human and nonhuman life itself.

Some radical lesbian feminists argue that the notion 'equality' is tethered to a view of human nature that so privileges attributes traditionally associated with men (aggression, hierarchical forms of organization, rugged individualism, competition, and an ethics focused on impersonal rule-following over relationality), that women are only able to be included within such conceptual frameworks as honorary men. It is little wonder, they argue, that examples offered to young women by liberal feminists as role models and heroines are modeled after male heroes; the accomplishments of women like Harriet Tubman, or Marie Curie (or movie heroines like those found in *Terminator II*, *Aliens*, *Femme Nikita*, *The Hunger Games*, or *The Girl with the Dragon Tattoo*) are valued according to a standard that rewards domination over domesticity, conquest over caring, and militarism over mothering – masculinity over femininity traditionally conceived. This is not to suggest that these are not examples of very real valor, but that what is rewarded in them goes further to reinforce a male-centered vision of the good than it does to foster a vision centered on 'feminine' identified values such as cooperation, compromise, collective decision making, or compassion. It is thus simply not enough, argue radical lesbian feminists, for women to settle for reformist programs that aim at an equality based on access to masculine values. Given the existing conceptual constraints, such programs will either fail or, even if they succeed, will do so only at the cost of continuing to devalue qualities associated with women and femininity.

Liberal feminism does not necessarily represent the desires or interests of all women, whether those desires are to be considered culturally constructed or endowed by nature. This thus brings us to what is commonly referred to as the essentialism versus antiessentialism debate; if what radical lesbian feminist conceptual analysis shows is that the ways we conceive of gender, sexual identity, and sexuality privilege men and we consider these to be a reflection of natural propensity, should not we then aim to elevate the value of feminine nurturing, emotional responsiveness, and the tendency to focus on relationships, over abstract autonomy? Or, alternatively, should we eschew traditional femininity characteristics as the construction of patriarchal culture, arguing that there are no essential qualities that importantly distinguish men from women?

The meanings of androgyny are instructive here. One meaning of androgyny favors the promotion of the masculine and the feminine in all of us, acknowledging that while gender may be constructed, such qualities may still be salvageable when reinterpreted in a nonsexist context. Another meaning of androgyny, however, suggests that we ought to abandon notions of femininity and masculinity altogether as unworkable in favor of some other notion of personhood. Here, the question that arises concerns what 'personhood' would look like, and whether it is possible to envision a 'human being' that can comprehend biological differences without reproducing an atomistic individual that it becomes subject to the same criticism radical feminists level at liberal feminism. Can we, in other words, envision a concept of 'embodied person,' which, irreducible to the determinations of either biology or culture, is rich enough to account for differences relevant to and affected by both?

A contemporary radical lesbian feminism is well equipped to address these questions since the atomistic personhood informing the essentialism debates is itself part and parcel of a 'nature' against which 'human being' is conceived as radically separate. A liberal feminist perspective might raise questions about the qualities described as 'masculine' or 'feminine,' whereas a radical lesbian feminist approach queries whether the atomistic conception of 'person' is itself defensible. Well illustrated by the facts of climate change, the radical feminist critique shows that the atomistic conception of personhood divorced from the necessary conditions of life – clean water and breathable air – is likely vulnerable to conceiving itself as, well,

invulnerable. When masculinized 'not dependent,' 'autonomous,' and 'self sufficient' describe the atomistic 'person,' nature can only be conceived as a resource whose value is not existential, but commodifiable.

Moreover, a personhood conceived as invulnerable is also likely to be conceived as infinitely adaptable – a human, all too human, trait that is both beneficial and damning. We may be able, for example, to adapt to some of the environmental and geopolitical demands of a warming climate, but like the proverbial frog in the pot of warming water, we will reach a point where adaptation will not prevent disaster. By demonstrating that the essentialist debates over 'masculinity' and 'femininity' are really symptomatic of deeper issues concerning how we conceive 'human being,' radical feminists show how one such conception – atomism – has become institutionalized not only as male privilege over women, but human privilege over nature – with potentially catastrophic consequences.

Radical Lesbian Feminism and a Radicalized Socialist Lesbian Ecofeminism

However we settle the essentialist debates, the history of heteropatriarchy shows that the oppression of women is sanctioned through the denigration of qualities identified as feminine. Whether we seek liberation through the elevation of, or the abolition of, femininity, what remains clear is that reformist programs for inclusion can never be adequate. Another possible avenue of critique of heteropatriarchy, one that skirts the essentialist debates, is that offered by Marxist/socialist feminists who show, given the marriage of patriarchy to capitalism, that it is illuminating to conceive of women not as a group but as a class whose oppression is maintained through economic means. This notion fits neatly with analyses that identify atomistic personhood with the commodification of nature, since to conceive of women as a class is to conceive women in terms of the commodity value of their labor. As Frederick Engels argued, the very first commodity is women's capacity to produce – paid work and unpaid domestic labor – and reproduce – produce labor for the next generation. So too nature; commodified first as resource and then conceived as interminable or endless, it is really no wonder that for marketing purposes, nature is feminized and women are naturalized. Both effectively marry patriarchy to capitalism in that both are subject not merely to domination, but exploitation conceived as having no natural point of exhaustion. Ironic it is then, that it is female-sexed reproductive systems that are especially vulnerable to cancers linked to environmental pollutants – for example, diesel, associated with climate change.

Combined with a radical lesbian feminist analysis of patriarchal concepts of motherhood and domestic labor, a Marxist/socialist account shows how divisions of labor are sexed in at least two ways: first, because women's *labor qua* procreation is assigned to the 'natural' it is not counted as labor at all, and second, because the domestic family-related labor performed predominantly by women has become 'naturalized' in a capitalist economy that identifies all labor that is not paid or wage as not labor. Cast as the vehicle for the reproduction and sustenance of life, 'woman' becomes a paradox. 'She' is unexploitable since her labor is not counted as labor under capitalism, yet 'she' also epitomizes the very prototype of exploitability in that 'her' labors are systematically and maximally undervalued, which, in a capitalist system means un/undercompensated.

A necessary point can thus be made without entering the essentialism/antiessentialism debate, the fact that women's oppression is intimately linked to the relationship between her economic status and her status as provider of hearth, home, and progeny for men, well supports the radical lesbian feminist claim that there are no social institutions in which men do not have a controlling interest, including economy and family. What recommends this approach over liberal feminism, then, is the emphasis on the role of economic class. The best that liberal feminists can hope for is a reform leading to an equality of competition between men and women within capitalism, whereas the radical Marxist/socialist feminists are free to imagine a revolution leading to a utopian world within which neither sex nor class oppression are operative – much less determinative – of social status.

While a radicalized Marxist/socialist feminism goes further than liberal or radical lesbian feminism alone to evaluate capitalist heteropatriarchy and offer an alternative, even it ultimately fails the project of genuine emancipation. For while such a critique of capitalism shows something important about the sexed parameters of economic oppression, there remains considerable work to show the relationship between economic and other forms of oppression such as sex, sexual orientation, race, age, ability, and so on. Here too, however, an expanded radical lesbian feminism has something important to offer; because each form of oppression is linked in to conceptions of 'nature,' each may be evaluated in terms of the ways in which they support not only oppression, but exploitation of the natural and nonhuman animal world. That persons of African descent are, for example, commonly animalized in pre–Civil War defenses of slavery while nonhuman animals are humanized in stereotypically heterosexualized ways, indicates that what governs the ways in which we conceive of race is essentially heteropatriarchal.

Given the need for this level of analysis, many radical lesbian feminists distinguish themselves from both mainstream liberal feminism and Marxist/socialist feminism by taking a more skeptical, self-reflective approach to theorizing, arguing that it is at least an open question whether any patriarchal institution is salvageable in any form. In a world dominated by climate change, this question becomes especially pointed. There is little more revolutionary a declaration than that multinational capitalism, including Big Energy, Big Box, and Big Pharmaceutical, must be overthrown, but if this is not accompanied by the overthrow of other patriarchal institutions such as the legal definition of family as male-headed, the status of women could remain unchanged or worsened as men's conditions improve. What revolutionary changes would institutions like the family need to undergo to achieve equality not only with respect to gender, but also with respect to any number of other axes of oppression, including race, ability, economic class, indigenous culture status, age, sexual identity, and sexuality?

Some radical lesbian feminists such as the late Mary Daly argued that patriarchy must be overthrown or abandoned in

favor of separatist or women-only cultures and societies. In her 'radical elemental feminist manifesto,' *Quintessence*, Daly describes the fundamental ideology of patriarchal institutions as rapist, "characterized by invasion, violation, degradation, objectification, and destruction of women and nature; the fundamental paradigm of sexism, racism, classism, speciesism, and all other oppressive-isms" (1998: p. 8). Not unlike the radical Marxist/socialist feminist's view that the sexed division of labor lay at the root of economic exploitation, Daly argued that at the root of all forms of oppression lay a very particular form of sexual domination – the male prerogative to rape – and that this form of sexual enslavement then becomes the naturalized condition of virtually all nonmale, nonwhite, nonheterosexual, non-Western, nonhuman, and nonaffluent persons.

If Daly is correct, (1) all forms of oppression and exploitation take sex as their essential archetype. Hence, (2) feminism's emancipatory objectives cannot be achieved without serious attention paid to the ways in which sexism informs the other 'isms' that sustain a patriarchy that (3) is oppressive as well as violent in all of its past and present forms, and in which its primarily male beneficiaries continue to have a stake. Finally, (4) to whatever extent sex oppression is archetypal of all oppression so too must heterosexuality become compulsory, that is, a characteristic of the heteropatriarchal way we define sex and hence sexuality such that other sexualities are either completely occluded or, when acknowledged at all, identified with the perverse and unnatural.

Within compulsory heterosexuality, an action only counts as sex if (1) it involves a penis penetrating a vagina, (2) it is compulsory in the sense that no other option counts as an acceptable choice, and (3) it negatively associates abstinence from such sex with frigidity, mental illness, or homosexuality. On this view, then, the domination of sex cannot be accomplished without the domination of sexual identity and sexuality. Given the combined compulsion of (1)–(3), moreover, it is little wonder that Daly characterizes heteropatriarchy as rapist and thus resistance to patriarchy requires resistance to heterosexuality. Radical feminism thus becomes radical lesbian feminism as both the rejection of male sexual access and as the radical embrace of the value, lives, and bodies of women. Such is the meaning of dismantling the master's house with new tools. That is, radical lesbian feminists (or radical feminist lesbians) argue for two distinct but intimately related claims: that compulsory heterosexuality must be repudiated, and that lesbianism must be theorized as a positive, life-affirming, morally responsible choice.

One common objection to this view is that it is possible to embrace the political goals of radical lesbian feminism without jettisoning sexual relationships with sympathetic men. However, because even the most sympathetic of men are still disproportionately empowered in heterosexual relationships, such intercourse cannot fail to remain compulsory, argues Daly (among others), and hence self-defeating. This is not to say that heterosexual sex is inherently harmful to women, but rather that because male sexual access is one of the primary sources of women's oppression, cauterizing this source of harm is instrumental to ending heteropatriarchal power. Indeed, whether heterosexual sex is inherently harmful or not is beside the point given that, from a radical lesbian feminist point of view, it is hard to imagine conditions under which the potential for harm could be sufficiently ameliorated. Nothing, moreover, requires us to theorize men's 'essential' natures as aggressive or women's as passive; it is enough to recognize that history and culture are so saturated with the glorification of male sexual conquest and violence, that the prospects for change and the likelihood of that change being initiated by men is almost nil. Like Marx's conception of the permanent revolution of the working class, radical lesbian sexual separatism constitutes more than a political strategy; it constitutes the bedrock of a growing lesbian culture, a revolutionary positive choice to live one's life among women, not among women who are waiting for men to learn to behave better. Indeed, to opt merely for the latter is tantamount to abandoning in advance the worth of having chosen the former.

Feminists such as Sarah Hoagland argue that a constitutive feature of a lesbian ethic includes the repudiation of all forms of domination and subordination. To the extent, then, that heterosexuality is entrenched in and defined by these values, it can find few comfortable bedfellows – literally or figuratively – among radical lesbian feminists. Is a nonoppressive, non-dominating heterosexuality possible? In theory, no doubt it is. But, as feminist philosopher Marilyn Frye points out, the practical likelihood of this seems illusive, given the stakes men are likely to continue to have in heteropatriarchy. Lesbians, she argues, are simply impossible within the heteropatriarchal framework. Frye goes on to argue that given the biological, social, and political expectations attached to reproduction and child rearing, it is no wonder that exercising control over pregnancy, birth, and lactation becomes imperative for men who, without control over these, would experience the unjust withdrawal of privilege. As Frederick Engels had shown more than a century earlier, men's investment in sexual domination is rooted first and foremost in men's investment in the products of their own (hetero)sexuality, namely, the offspring who represent a form of property, a reflection of self-interest, and the potential for future inheritance. To deny men sexual access, then, is effectively to deny them the opportunity to control the conditions of women's reproductive lives, and hence of women's lives in general. Note that here too, an element of Marxist/socialist critique helps to forge the tools of radical feminist critique, especially, concepts like 'property,' 'product,' and 'inheritance.'

The affirmation of women's lives, bodies, values, and choices forms the second critical axis of any radical lesbian feminist theory. Yet, while this affirmation is often theorized as necessitating some separation from men – separatism – it is unclear what exactly this means, for whom it is realistically practicable, and to what extent it requires physical and material independence from both men and patriarchal institutions. This much, however, seems clear: the choice to no longer engage with men sexually constitutes a minimal criterion of separatism, whereas the choice to embrace a life composed primarily or even exclusively of 'women loving women' goes much further and is more difficult to realize in practice. There are several reasons why this separation is often impracticable: first, because we live in a multinational capitalist economy, wherewithal is economic wherewithal. Hence, the creation of any women-only space, permanently (e.g., a communal organic farm) or temporarily (e.g., women's music festivals) is an economic undertaking that is always at risk of excluding

some in favor of those who can afford separatism. As some lesbian feminist women of color point out, separatism continues to be a luxury of whiteness to whatever extent economic affluence does. Second, because every economic, social, cultural, medical, and political institution, to which we have access, is imbued with heteropatriarchal values, it remains somewhat obscure what separatism could mean short of wholesale abandonment. Third, short of the invention of parthenogenesis, a contribution of male-produced sperm is still requisite to human reproduction.

Such a characterization of separatism may, however, be guilty of straw fallacy; maybe it appears impracticable only because its parameters have been defined too narrowly or too simplistically. Whether this is so, however, depends precisely on what kind of conceptual work such a notion is supposed to be able to do, for whom, and for what duration. The range of other potentially separatist choices is very wide and includes at least the following: the formation of one's primary affective relationships, sexual or otherwise, with women and girls only; choosing a woman-centered spirituality; adopting and rearing girls within a lesbian culture; creating woman-centered works of art, dance, music, poetry, comedy, film, philosophy, and literature; rejecting male-centered practices such as nonhuman animal flesh consumption, hunting, or other hierarchical forms of organization; choosing political affiliations and activities that are consistent with a woman-centered life. The difficulty here, of course, is twofold: first, how ought what counts as woman-centered or lesbian (and do these mean the same thing?) be defined? How ought the reproduction of the same disabling forms of heteropatriarchal oppression be avoided within such a lesbian culture? (Should preoperative transsexual men-to-women be allowed into women-only spaces? Can a woman-centered life include rearing sons? Should radical lesbian feminists form political alliances with gay men?)

Second, if 'separatist' is itself subject to evolving cultural, ethnic, and historical interpretation, surely it is as dangerous to treat it ahistorically as it is to treat 'woman,' 'man,' and so on. What, then, does separatism require beyond the refusal of sexual access by men? Can lifelong lesbians who do not identify as feminists be considered separatists? Can women who have left long-standing heterosexual relationships and now identify as lesbian qualify as separatists in midlife? How separate is separate? The point, of course, is that many questions attend the endeavor to create new tools, and much more attention needs to be paid to the ways in which oppressions related not only to sex, but to race, ability, age, gender expression, and class intersect with compulsory heterosexuality. However, the questions that continue to haunt lesbian separatism do not detract from the power of radical lesbian feminist analyses of heteropatriarchal institutions. Indeed, questions about any utopic vision of the future – lesbian feminist or otherwise – are central not only to feminist theory but also to environmental philosophy. Whether future environmental conditions can sustain communities in any fashion desirable to humans and for a diversity of nonhuman life is an open question. If anything, in other words, makes the vision of a lesbian utopia seem naïve or unrealistic, it may not be whether separatism should or should be a goal; it may be whether future conditions for life are sustainable at all.

All human communities are threatened by climate change – some more than others. An ecologically oriented radical lesbian feminism need not set aside issues concerning heteropatriarchal privilege such as the attractions of separatism, transsexual identities, and so on, but must theorize them in light of the reemergence of a heteropatriarchal power that is unprecedented in human history, namely, that of multinational corporations that effectively control the conditions of life itself. I have made my focus industrialized fossil fuel extraction, but we could also have included the power wielded by corporations like Monsanto, factory farming, and the pharmaceutical giants. In any of these cases, radical lesbian feminism occupies, I suggest, an excellent position not only to evaluate the heteropatriarchal character of these global corporate enterprises, but to offer something essential in light of the threat posed by climate change, namely, the conceptual, moral, and practicable framework for the revolution necessary to end what amounts to corporate fascism, and with it a trajectory toward ecocide.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin
June 2001

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Fertility and Culture: Anthropological Insights

Caroline H Bledsoe, Northwestern University, Evanston, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Between the fertility event that increases a population and the cultural ideas that shape how it is perceived and analyzed lies an engaging set of issues. To grapple with them, demographically oriented approaches to fertility, and to reproduction more broadly, have increasingly sought insight from sociocultural anthropology and its longtime concern with the ideas by which people understand their worlds. The results, despite the vast differences in method and philosophical orientation that typically separate demography and anthropology, are forging new ways to look at fertility. This article addresses the recent history of the anthropology and demography relationship in studies of fertility, focusing especially on developments that take culture as a fluid and contested set of mental schemes.

In its narrowest demographic meaning, fertility refers to the production of a living child that adds one person to a population. Sociocultural anthropology's mainstream has never been interested in the question of numbers that this definition implies, at least to the extent that demography has, in its focus on population's stocks and flows. Conversely, the anthropological penchant for rich, contextualized cultural meanings has drawn limited interest from demographers seeking parsimonious ways to describe and explain fertility's quantitative patterns. Despite their profound differences in core methods and philosophical orientation, though, both demography and its 'softer' neighbors appear to have benefited mutually, in recent decades, from their collective engagement with reproduction. This article focuses on demographically oriented studies of fertility specifically, and of reproduction more broadly, that have drawn cultural insight from anthropology, which this article will take to mean sociocultural anthropology. Contributions by authors in related fields such as sociology and history that employ anthropology's ethnographic methods (participant observation, open-ended interviews, text analysis, and so on) will be noted as well. This article focuses on anthropology's classic strengths in culture and its insistence on close attention to local perceptions of demographic phenomena. It will show that between the fertility event that increases a population and the cultural ideas that shape how it is perceived and analyzed lies an engaging set of issues. (Biological anthropology's emphases on the genetic and evolutionary causal bases of fertility are amply covered elsewhere in this Encyclopedia.)

Demography seeks to identify and measure key variables related to population and to demonstrate relations among them. To frame its questions and explain its findings, it has tended to draw on disciplines such as sociology, economics, history, and statistics. In recent years, some demographers have turned as well to anthropology and its methods. One source of inspiration was the enormously important Princeton European Fertility Project (Coale and Watkins, 1986), in which the decline in marital fertility in Europe was found to be related less to conventionally expected economic factors, especially levels of income and development, than to religion, dialect, ethnicity, and region – factors the project termed 'cultural.' According to Lesthaeghe (1977), for example, Belgian villages experienced fertility decline according to their linguistic groupings. Walloon villages reached low fertility earlier than did Flemish villages, irrespective of their economic characteristics or locations within the country. The implication was that information about fertility reduction methods, the values placed on children, and so on, diffused more readily within culturally or linguistically similar regions than among those that differed significantly. The second reason why demography turned to anthropology has been an increasing interest in patterns of fertility and mortality in developing countries. As early as the 1960s, questions were emerging about the social supports for high fertility and about the tremendous variations in observed reproductive practices that researchers trained in Western quantitative disciplines felt poorly equipped to handle. Because anthropology is the social science that has so routinely dealt with non-Western societies, anthropologists' empirical work on these societies began to draw the interest of demographers. Increasingly, moreover, many demographic studies have gone on to directly incorporate the methods and concepts of the discipline they initially saw as such an exotic oddity. Many demographic studies are planned from the outset to incorporate, along with their conventional analyses of surveys and censuses, ethnographic field components and interviews. Even the largest demographic survey in history, the International Demographic and Health Surveys, began some years ago to offer a 'focus group' component in which statements and explanations, rather than simply numeric and short-answer responses, could be elicited.

How Has Sociocultural Anthropology Been Applied to Demographic Studies of Fertility?

Sociocultural anthropology, like other social sciences, seeks to understand why people think and behave the way they do; more so than most of its sister disciplines, however, anthropology has long seen thought and behavior as shaped by local socioeconomic contexts and by the power structures that determine advantage within them. In addition, anthropological work begins with the premise that the cultural frames from which our understandings of human motivation and action spring are likely partial, if not altogether wrong. They therefore

have the potential to be dangerously misleading. This is true, no matter how familiar the culture appears to be to the researcher. In fact, the more familiar the culture and the instruments that purport to describe it, the greater the risks of being misled by one's preconceptions, and the more wary the analyst should be. To a field whose practitioners start with the expectation of being wrong, the most valued methods are those that offer the most promise for capturing local people's own subjective experiences and the logic underlies their choices in the worlds in which they operate. Doing so, it is felt, should lead not simply to better understandings of the realities people experience, whether they live in close or distant places, but to a more encompassing view of one's own reality and hence to better theory. Though many anthropologists might disagree, there is no reason why Western-based quantitative methods and data should not be as useful as intensive, open-ended interviews for trying to understand experience and to unravel local logics and the insights they can lay bare. When they do study local beliefs, however, Western 'quantifying' traditions has tended to treat these beliefs as the end of the story: as objects to discover and report. Local beliefs are also frequently depicted in demographic works as 'cultural barriers' to more rational understandings, as Watkins (2001) and Peters (2010) point out, rather than as potential windows of ever-deeper insight for unraveling puzzles that Western scholarship has poorly understood.

Operationalizing Cultural Traits in Statistical Taxonomies

As promising as anthropology's approach and methods can be in demographic research, what anthropology has usually offered the demographic enterprise has largely reflected the state of its own field. In the middle of the twentieth century, for example, a particular methodological approach, sometimes called the cross-cultural method, dominated American anthropology. This was a kind of statistical taxonomy in which societies were described by traits that could be 'operationalized' – cast in the form of discrete variables that could be coded and counted in order to test quantitative hypotheses and look for cross-cultural patterns. The primary data used in this endeavor, the Human Relations Area Files (HRAF) (Murdock, 1975), contained detailed codes of the organizational features of hundreds of ethnic groups. Prevalent as well in American anthropology at this time were questions about the relationship of culture to personality from Freudian perspectives. A number of anthropologists sought to combine this theoretical agenda with cross-cultural methodologies. Harvard anthropologists led by John and Beatrice Whiting (Whiting et al., 1958), for example, argued from HRAF data that life under harsh environmental conditions required parents to protect a child by long periods of breastfeeding and a ban on sexual relations. For boys, such practices, because they were thought to produce strong psychological attachments between mother and child, were said to necessitate dramatic manhood initiation rituals that separated boys from their mothers and fostered the development of their masculinity. Though personality development itself drew limited demographic interest, there was considerable interest in the potentials of such studies to shed light on observed durations of breastfeeding and postpartum sexual abstinence, which had more obvious connections to fertility through its biological bases. Applying this kind of analysis to data on kinship and economic subsistence, demographer Frank Lorimer (1954) argued that populations like those on small islands, with highly constrained and intensively utilized resources, developed forms of social organization and customs that effectively checked family size. In Polynesia, he maintained, such customs included coitus interruptus, abortion, infanticide, the encouragement of sea voyaging by young men, and banning further reproduction to the mother of a married son.

Culture as Ideas and Mental Schemes

The taxonomic approach drew considerable interest in demography. Yet within the mainstream of anthropology itself, it drew increasing antipathy. Critics charged that this approach, in attempting to extract practices from the contexts in which they drew meaning and make them into checklists of discrete, modular traits effectively froze what were in reality multifaceted, fluid phenomena. Particularly with the impact of Clifford Geertz (1973), anthropology's increasing emphasis on the importance of culture and ideas shifted decisively away from such approaches and toward the in-depth search for shared mental schemes and symbols that gave clues to local interpretations of the world. By contrast to efforts to operationalize cultural data and to break them down into codified pieces that could be incorporated directly into a set of equivalent universal categories, most anthropologists now stress that culture cannot be broken down into separable pieces and that meaning must be understood within a context. Anthropologists also recognize that apparent cultural oddities may be important clues to some facet of a reality that the analyst has not seen and whose careful coding systems may therefore bury this reality.

Anthropologists' insistence on rescuing culture and the ideas it generates from the domain of operationalizable concepts has not always been easy to explain to other disciplines. The work of demographer John Caldwell, however, took a notable stand in its efforts to make culture figure more explicitly as ideas or attitudes. The most notable example is his description of the spread of Westernization throughout the developing world: the rise of new attitudes about work, family relations, and fertility practices, particularly through schooling and its perceived influence in changing values of authoritarian family structures, a distant and severe father, and marriage as an arrangement between elders. Caldwell (1980) describes primary school textbooks in three African countries as powerful statements of new values of family organization: parental closeness to children; kindly, understanding fathers; and love-match marriages. So powerful were these ideas said to be, that the shift to mass Western-style education may have generated a new cultural climate among all members of these populations, even those who had never attended school. These ideational changes, he argued, in turn facilitated a shift in values to the nuclear family and to goals of fewer children.

The evolutionary implications associated with traditional/modern frameworks have fallen out of favor with most sociocultural anthropologists, who reject any necessary assignation

of traditionalism or modernity to societal forms, and they recognize all societies as inherently fluid and changing. However, Caldwell's determination to take on culture as a set of shared mental schemes that might bear on fertility may have helped to pave the way for new efforts to theorize fertility and to understand the historical and social contexts that gave rise to different ways of seeing it (e.g., Johnson-Hanks et al., 2001; Charbit, 2010; Szreter and Fischer, 2010).

An engaging example that sought explicit links between belief and behavior was Cambridge historian Musallam's (1983) account of the allowable uses of contraception for men in classical Islam. Whereas Western analysts had seen Islam as opposing the use of contraceptives its practice, Musallam's emphasis on culture and the logical strands connecting it to empirical reality described a more complex picture. Contracepting, he explained, was indeed seen as an act that fell short of Islamic religious perfection. In practice, however, it allowed a surprisingly wide range of exceptions. Because contraception was allowed if it was intended to preserve health and well-being, a man could contracept if his actions were intended to protect a young nursing child from the nutritional competition posed by a new pregnancy. He could also take contraceptive measures to protect his wife, especially if she was young or sickly, from the dangers of childbirth, or simply to protect her health and beauty from the wearing effects of childbearing. In another major domain of concern, that of economic welfare, a man who found himself tempted to engage in theft to meet his financial responsibilities to his children could practice contraception to limit the number of his offspring to a manageable size. Yet exceptions emerged in debates over the ends to which one might legitimately go to safeguard his property. Because a man could not sell a slave after she became the mother to his child, using contraception was seen as a lawful measure to retain liquidity of his slave assets. Conversely, when having sex with another man's slave, it was argued that a man could use contraception to ensure that his own children would not be born into slavery. And, in parallel to this was the alleged need to safeguard the welfare of the Islamic community under conditions of warfare. If a man had sex with a woman behind enemy lines, he was expected to take contraceptive precautions, lest he risk not only losing his own children to slavery by procreating with her, but swelling the numbers of the infidels.

Culture in Flux; Culture in Contestation

Despite the intrinsic appeal of pursuing cultural pathways of logic like this, contemporary anthropologists and their like-minded demographic colleagues seldom pose such unproblematic straight lines between cultural belief and behavior. Furthermore, as Johnson-Hanks (2005) shows, the future is a far murkier place than older models of economic rationality have implied. There are surprisingly thin connections between reproductive intents at the beginning of reproductive life and later on (Johnson-Hanks and Miguel, 2011). Rather than pursuing singular cultural templates that constrain action; the future is best handled by managing flexible sets of interpretive resources as new challenges come into view (Johnson-Hanks et al., 2001). Even the most apparently unbending bodies of religious canon can be argued to have numerous potential interpretations (Musallam, 1983).

Indeed, one of the most lively examples of research that has demanded a fluid, resourceful vision of culture is the topic of male fertility. Fertility research is by far the largest subdiscipline in contemporary demography. Yet until the 1990s, women comprised are almost exclusive objects of study. Men, if they appeared at all, were shadows: partners-by-implication of those engaged in childbearing. At the same time, there are tremendous challenges posed in efforts to analyze male fertility. While some men claim they do not know how many children they have or deny connection to offspring born outside of wedlock, others claim to have fathered children they have never seen, while infertile Egyptian men in even the most apparently conservative of circumstances may seek to resort to whatever new global technologies promise to yield children, or even to fashion new masculine identities from local cultural repertoires (Inhorn, 2012). The fact that men so often try to manage aspects of parenthood can thus work to the disadvantage of children in instances where men seem to be edging out of commitments to children. But men's diverse parenting energies can also have clear advantages for children. Townsend's study of rural Botswana (2000) showed that in this place, where the demands of migrant labor were so taxing, a young man who lived full time with his children was an oddity, and hence many children grew up hardly knowing their father at all. As they grew older, however, and unable to hold such strenuous jobs in the minds, men provided considerable support for many children, including those of other men, whether these were uncles, grandfathers, or fictional cousins. As this example suggests, persistent perceptions in the international population policy world of massive male disengagement from parenthood responsibilities, along with Western cultural preoccupations with the biological side of paternity, have masked some critical variations in the cultural handling of fatherhood.

One of the most important points of debate in current sociocultural theory that is now being brought to demography is the extent to which demographic patterns stem from politics and economics versus individual agency. That is, to what extent are people's choices limited by wider powers beyond their control? Can they, on the other hand, make their own decisions about reproductive actions by resisting or evading state powers? Carefully conceived studies that analyze demographic questions through anthropological lenses increasingly suggest that both forces are invariably at work, and that cultural ideologies are often at the center of the contestation. Greenhalgh and Li's account (1995) of the heavily enforced Chinese state policy of one child per couple that was implemented in 1979 reveals a dynamic of mutual influence. As their analyses show, women began to resist the formal one-child policy, strategizing to have two children, especially if the first was a girl. To disguise their efforts to ensure a boy, women attempted to adopt out daughters, move to another city to give birth to a second child, remove state-imposed intrauterine devices from their bodies, conceal unauthorized pregnancies until it was too late for a state-required abortion, and (as ultrasound technology spread) engage in sex-selective abortions. By 1991, the state, faced with such resistance, was forced to begin to rewrite the policy. It 'encouraged' one child for all and prohibited third child, yet allowed two children if the first

was a girl. As Greenhalgh and Li caution, however, individual women may have been liberating themselves individually from unwanted daughters, but their strategies of resistance effectively reinforced the state's gender hierarchy.

The fact that culture is increasingly seen in anthropology as a resource that people may put to use is best examined in a context in which consciousness about the effects of action on fertility and reproductive volition in general have been seen as low. For this reason, some of the best examples are found in topics related to high fertility: a pattern that has been seen in demographic convention as an outcome of biology and custom and not as the calculus of conscious choice (Coale, 1973). In populations said to have had what has been called natural fertility (Henry, 1961), the demand for children is high, and the number of children women produce is assumed to be limited only by how quickly they can be supplied, given the biological rhythms resulting from specific customary regimes. In sub-Saharan Africa, for example, substantial numbers of people continue to report on surveys that they want 'all the children God gives them,' and typical reactions to suggestions to reduce fertility range from polite interest to outrage. By contrast, in societies where desires for large numbers of children have abated, couples are said to engage in parity-specific behaviors, especially the use of modern contraceptives, in order to control completed family size.

However, ethnographic accounts of practices such as infanticide, child fosterage, child abandonment, adoption, and abortion make it clear that reproduction can be subject to many means of control, and that people may readily resort to them. Whereas Western models assume, for example, that reducing fertility is the best way to address economic troubles, families in many African societies see the diverse skills and social ties that they manage to cultivate through a diverse range of children as the key to their future capacity to cope with economic and political adversity. The widespread use of child fostering is a case in point. Young children are commonly fostered to 'grannies'; later, when they are older, they may be sent to urban households that offer training in specialized apprenticeships or a chance to attend a respected school. Adults, in short, treat the original biological event of parenthood not as a secure hold on a child's future support, but as the beginning of a long, continuously negotiated relationship in which they try to influence children's obligations. While Western family planning programs in developing countries continue to emphasize child numbers and the economic woes they intensify, many African families would find this as a drastic solution. They prefer to have a number of children, cultivating differentiated opportunities for them (Bledsoe, 1994).

Another example of people's efforts to exert control over childbearing appears in the cultural reinterpretation of contraceptive technologies in sub-Saharan Africa (Bledsoe, 2002). In Western cultural perceptions, contraceptives are devices that limit fertility, and people who do not wish to limit births would be unlikely users of devices that would do so. In West Africa, however, people see contraceptives more as devices to ensure the survival of many children by spacing their births carefully than to limit them. Some of the most common contraceptive users are thus breastfeeding women who want to avoid overlapping children, one in the womb and the other nursing, but who have resumed their menses before the breastfeeding child can be weaned. Families exert prodigious efforts to control the timing and circumstances of children's births, though, again, not necessarily to limit numbers of children.

Reconciling Local Cultural Knowledge and Western Science

Pursuing threads of counterintuitive cultural logic that are opened up by scrutinizing demographic patterns can yield not simply observations about culture but empirical truths that have been lost to contemporary scientific view. The example of contraceptive use in West Africa (Bledsoe, 2002) plays out in striking ways, shedding new light on the cultural ideas that inevitably influence the development and interpretation of even the rigorous Western quantitative methods.

Contemporary Western writings, both scientific and humanistic, depict the ability to bear children as one limited by time. That is, Western culture posits a time-dependent ability to conceive as the key to achieving fertility. Accordingly, the number of children a woman may bear is calculated by dividing the total amount of time she can conceive by the interval required for each pregnancy. The use of contraception plays directly into this presumed calculus. To the extent that the use of contraception or abstinence blocks off time in this potential reproductive span, a woman's fertility will remain low. In the African cultural view, however, the ability to reproduce is limited not by time but by bodily resources. Among the forces that drain bodily resources and terminate the ability to reproduce, childbirth is by far the most powerful. Each birth takes a mounting toll on a woman's physical reserves, cumulatively 'aging' her body (or wearing it out, in many local translations), and eventually making further childbearing dangerous, irrespective of her chronological age. In this vision, aging is not the same thing as age. Although aging tends to be equated with the passage of time in Western analyses, its pace, in the African view, is contingent on the physical ordeals of the body suffers. Difficult and/or closely spaced births, combined with a poor diet, illness, and strenuous work responsibilities, can exact a disproportionate toll. In such situations, a woman who is trying to have all the children God gives her will almost certainly run up against the anatomical and energy limits of the body before she runs into any temporal boundaries on the ability to conceive. Because contraceptives allow women more opportunity to recuperate between births, and because reproductive capacity is seen as governed by taxing events rather than by time, it is clear why contraceptives can be used to produce more, rather than fewer, children and even to stem the pace of aging.

The African vision of contingent wear and cumulative physical toll over a reproductive lifetime might appear to be 'just common sense.' It is more accurate, however, to say that our increasing personal distance from the high-and-risky end of the fertility horizon, combined with our unprecedented levels of preventive care and copious backup in case of emergencies, has sharply truncated our vision of the tolls that reproduction can take under conditions that we no longer experience or fully understand.

Future Possibilities for Anthropology and Demography in Studies of Reproduction

As these examples suggest, anthropology's style of engagement with demography and the insights to gain from such mergers will continue to change as the fields themselves change. In the evolving relationship between anthropology and demography, moreover, the spectrum of topics continues to broaden. New common interests continually arise in the politics of fertility control, new fertility technologies, gender and sexuality studies, the negotiation of fertility decisions among spouses, and the continual return to scrutinize the taken-for-granted bases of fertility (Petit, 2013; Verheijen, 2013).

Finally, while anthropology may have made itself as a discipline on the study of exotic people living in distant places, increasing numbers of practitioners are coming 'back home,' studying social and cultural phenomena in the urban United States and Europe. They are also experimenting with new forms and blends of data. These trends are facilitating bold new demographic and cultural projects, involving studies of almost unprecedented scope and creativity (Kertzer and Arel, 2002; Watkins and Swidler, 2009). Some of the most productive areas inspired by the determination on the parts of many to break down the quantitative/qualitative barriers lie in studies of migration. New anthropological interests in globalization are coming at the time when demographers are taking up the challenges of studying international migration policies that may separate parents and children, or create entirely new ones (Coe, 2013; Leinnaweaver, 2013). Indeed, the opening of the European Union and, in the United States, the removal of national-origin quotas for immigrants that have spawned migration across national borders on such an unprecedented scale are creating virtually uncharted forms of reproduction and reproductive careers. The continual emergence of patterns like these underscores the utility of past insights into population and culture; at the same time, it decisively challenges any confidence we might have entertained that these notions will suffice to understand population and its reproductive novelties across time and space that unfold almost daily in the national and international press.

Fertility and Social Networks

Abstract

Social networks receive an increasing emphasis in theories of fertility change. In contexts where modern family planning constitutes an innovation, as well as in contexts where fertility has declined to very low levels, interaction in social networks can affect the spread of new ideas and methods of fertility limitation. Social interactions can also shape norms and schema related to childbearing. This article first explores the theoretical arguments that explain why social networks are relevant for understanding fertility behavior. It then presents evidence that social networks exhibit important influences on contraceptive behavior and fertility, and it discusses the implications of social networks for understanding fertility dynamics.

Explanations offered for fertility decline in both developed and developing countries underwent fundamental changes in recent years. In addition to more refined economic reasoning and the introduction of cultural aspects, theories of the fertility transition now routinely reserve a place for diffusion and/or social interactions effects. Such effects arise because individuals are themselves members of larger groups. The information that is known to group members, the choices they make, the schemas they hold, and the norms and values they adhere to, can all exert a powerful influence on individual incentives to innovate and change behaviors. In settings in which fertility has been high, for example, innovation might take the form of adopting modern contraception and fertility limitation. In low-fertility settings, social networks can also shape norms and schema related to childbearing, or affect individuals' perceptions about the trade-offs entailed with having and raising children. Social interaction with group members represents one important avenue along which such innovative demographic behavior can diffuse: peers, community members or relatives may provide relevant information to potential adopters of family planning, they can affect the schema that guide individuals' behaviors with respect to life-course planning and parenthood, and they also represent the institutional and social structures that may facilitate or constrain individual fertility or family planning decisions.

Theories of diffusion and social interactions usually encompass two central elements. First, they emphasize a particular set of social interactions that are associated with the adoption of innovations, such as social networks, opinion leaders, public media, etc. Second, diffusion models have an explicit dynamic dimension in which the adoption of an innovation is often associated with 'contagion' or 'tipping point' phenomena, which can accelerate social change; there may also be 'conjunctures' that represent specific short-term social contexts within which decision-making often occurs.

Because fertility transitions are often rapid, irreversible, and only weakly associated with the specific socioeconomic conditions in a population, such diffusionist explanations have appealed to demographers ever since the European Fertility Project was carried out (Coale and Watkins, 1986). At the same time, diffusionist approaches have been criticized for several key reasons, such as the unclear definition of what diffuses the unclear connection with economic models of behavior or other models of individual decision-making, the mostly indirect empirical evidence, and the insufficient knowledge about the preconditions for the onset of the diffusion process. Several of these potential problems can be overcome by investigating the diffusion process with the tools of social network analysis.

Why Social Networks Matter for Understanding Fertility

The theoretical perspective of social networks rests on one central insight: human action is not carried out by individuals who make their decisions in isolation and independence, but by socialized actors who are deeply rooted in their social environments. These environments consist of other individuals with whom a focal actor stays in various relationships such as kinship, love, friendship, competition, or business transactions. Within these relationships, norms and schema about fertility and parenthood are negotiated and enforced, and information and goods are exchanged (Mitchell, 1973; Johnson-Hanks et al., 2011). On the one hand, this implies that a network member has access to resources owned by other network partners. In addition, a network enables its members to use the resources of community members to whom they are tied only indirectly. Social networks, therefore, constitute a pool of resources, which form opportunity structures for action (Lin, 1999). The kind and quality of these resources are decisive for the goals that are attainable for the network members. On the other hand, social relationships create, maintain, and modify attitudes (Erickson, 1988). People feel uncomfortable, if the attitudes of their network partners are too different from their own. Social networks, therefore, bring the attitudes of their members in accordance with each other. Alternatively, if the network fails to bring attitudes into conformity, the relationships become less intensive or are abandoned.

The resources that are available in a network, and the tendencies toward similar attitudes, depend on the characteristics of individuals' direct relationships with one another as well as on the structure of the entire network. One basic characteristic of network relations is their strength (Granovetter, 1973). Strong relationships, i.e., relationships that are characterized by a high frequency of contact or by a high level of emotional intensity, can be influential because they tend to transfer more

valuable goods, more binding norms and more trustworthy – but also more redundant – information. On the other hand, a fundamental dimension of the network structure is its density. A dense network, i.e., a network in which a high proportion of the individuals are in direct contact with one another, can lead to a high degree of normative pressure on its members and it can provide intensive support for members in situations when help is needed. Less-dense networks are characterized by a greater degree of heterogeneity. Such networks provide more opportunities for individual development, and they are the source of more diverse and heterogeneous information.

The mechanisms by which social networks affect the diffusion process can be summarized under the headings 'social learning,' 'joint evaluation,' and 'social influence' (Bongaarts and Watkins, 1996; Montgomery and Casterline, 1996). At early stages, potential adopters need to be informed about the existence of new methods of fertility control, their availability, costs and benefits, and possible side effects. 'Social learning' is defined as the process by which individuals (1) learn about the existence and technical details of new contraceptive techniques, and (2) reduce the uncertainties associated with the adoption of these methods by drawing on the experience of network partners.

The spread of information about modern contraceptives is always accompanied by the spread of new ideas about the social role of women, the status of the family, and the desired number of children. 'Joint evaluation' refers to the fact that social networks (1) facilitate the transformation of these new ideas into terms that are meaningful in the local context, and (2) assist in the evaluation of the respective social changes. A woman's decision to adopt a modern form of contraception, however, rests not only on information, conviction, and discursive evaluation, but also on the normative pressures of dominant groups or actors. 'Social influence' describes the process by which an individual's preferences, attitudes, and schema related to parenthood are influenced by the prevailing norms and values of the social environment. The direction of this social influence can differ in different stages of fertility decline. In the early stages, social influence may constrain the adoption of contraception, which demographers may interpret as being in a woman's best interest, because deliberate control of fertility is still considered deviant. Once a noticeable fertility decline has set in, however, the direction of social influence can shift. As low fertility becomes commonplace, the interaction among women or couples is likely to encourage a decline in the demand for children and behaviors that lead to a limiting of fertility, while at the same time, social interactions start to have important reinforcing influences on the postponement of fertility to older ages (Kohler et al., 2002).

Empirical Evidence

The earliest systematic evidence for the influence of diffusion processes and social networks on fertility decisions is found in two seminal analyses of demographic change. First, the European Fertility Project (Coale and Watkins, 1986) showed that areas which are culturally similar, in language or ethnicity, for example, often exhibit similar fertility patterns despite substantially different socioeconomic conditions and development levels. Thus, new ideas about fertility as well as new contraceptive methods seem to have diffused within cultural and linguistic boundaries. More sophisticated approaches employing similar methodological ideas have used the correlation pattern in pooled time series to show support for the role of social interactions in the adoption of family planning over time (Montgomery and Casterline, 1993). Second, the Taichung family planning experiment in Taiwan (Freedman and Takeshita, 1969) used a randomized experiment and longitudinal follow-up to show how direct interventions of a family planning program targeted to some individuals spread to others who were not directly contacted by the program. The study thus suggests that family planning interventions extend beyond the direct effect on the contacted individuals and that interaction in social networks constitutes an important aspect in the diffusion of new contraceptive methods and ideas.

The above evidence, although intriguing, is far from conclusive. In all of these data, the evidence is indirect and based on correlated fertility developments in geographically and/or culturally close populations. Related early evidence on microdata has often not been able to conclusively document influences of social networks on fertility decisions because the analyses identified associations between social networks and fertility outcomes, which may not represent causal effects of networks on fertility outcomes when networks are formed endogenously and are characterized by homophily and/or network members are subject to shared unobserved environmental influences (Manski, 1993). To overcome these limitations, the recent literature aimed at identifying social interaction effects on fertility and fertility-related behaviors has therefore used longitudinal data on social networks and family planning use (Behrman et al., 2002), focused on interactions among siblings (Lyngstad and Prskawetz, 2010), used instrumental variable approaches with the identification assumptions that some aspects – like physical attractiveness – directly affect friends' fertility behaviors but only indirectly affects respondents' fertility behaviors through social interactions (Card and Giuliano, 2013), exploited nonlinear variation in child allowances that provide differential incentives for having more additional children (Manski and Mayshar, 2003) or used 'natural experiments' in which structural reforms (like education reforms) differentially affected the childbearing decisions of siblings (Monstad et al., 2011). There has also been renewed attention from qualitative researchers in trying to unpack the relationship between interactions in social networks and fertility behaviors. In the context of relatively high fertility, the work of Watkins and collaborators in South Nyanza, Kenya, for example, demonstrated that casual conversations about family planning occur frequently as women go about their daily activities (Kohler et al., forthcoming). The network partners in these conversations are usually geographically and socially close to one another and are of a similar age or education. Frequently, they also know each other and share multiple relations, e.g., stemming from money lending, help in the household, or family ties. Related recent studies have highlighted that similar influences of social networks affect fertility behavior also in low-fertility contexts (Bernardi, 2003), including particularly the intentions to have children (Balbo and Mills, 2011) and the differential effect of strong and weak ties on fertility decision-making (Keim et al., 2013).

Besides having been challenged in terms of providing an adequate identification of causal effects of networks on fertility

outcomes, a further criticism of existing empirical work has been that the link between the theoretical arguments of why social interaction matters and the respective empirical implementation is weak in many analyses. One possible way to overcome this limitation is to use additional information about the structure of the social network, e.g., the density. Dense networks impose more behavioral constraints on the adoption or nonadoption of family planning than do sparse networks, which are more open to innovative information and behavior. Thus, density can be used as an indicator for the mechanisms of 'social influence' and 'social learning.' If the prevalence of contraceptive use in dense networks is more relevant for the decision to adopt contraception than it is in sparse networks, then social influence is the most relevant aspect of social networks. If it is the other way around, however, then it is social learning that is the dominant component. In the South Nyanza district of Kenya, for instance, evidence for both pathways of influence can be found. Moreover, the relative importance of these two mechanisms depends on the socioeconomic context of the regions. Social learning seems to be relatively more important in areas with higher levels of market activity (Kohler et al., 2001).

Although the empirical evidence supporting the argument that social networks play an important role in fertility decisions is accumulating from various sources, it remains inconclusive in important aspects, e.g., as regards the empirical identification of causal network effects or the mechanisms through which social networks affect fertility and related behaviors. There is also a need for new theories that conceptualize fertility behavior as an unfolding process over the life course that is influenced by schemas, material conditions, and social interactions (Johnson-Hanks et al., 2011). Nevertheless, the extensive efforts currently in progress to collect data, combined with both an improved theoretical understanding of social interaction and a more sophisticated empirical methodology, are likely to reveal further insights.

Implications of Social Networks for Fertility Change

Current research on social networks and fertility is in part stimulated by the fact that the dynamic implications of fertility models that include social interactions seem to be more consistent with the empirical evidence on fertility transitions than individualistic models. However, specific theoretical analyses of social interactions and fertility decisions are required as further support for this conclusion. Early formal models treat the diffusion of low fertility in a similar manner to the way the spread of contagious diseases is treated in epidemiological models (Rosero-Bixby and Casterline, 1993). More recent developments have used stochastic processes or agent-based simulation (Kohler, 2001; Diaz et al., 2011), with models explicitly considering the interplay between social networks, fertility decisions, schemas, and economic incentives within an evolving social context (Johnson-Hanks et al., 2011).

The main consequence of interactions in social networks is that fertility decisions of women or couples in a population become interdependent and exert mutual influences on each other. The implications of this interdependence can be illustrated in a simple nonlinear model of social interaction (**Figure 1**). The discussion focuses on social network influences on contraceptive adoption, and the framework has been analogously applied to explain the emergence of lowest-low fertility (Kohler et al., 2002; Lois and Arránz Becker, 2014) and teenage childbearing (Card and Giuliano, 2013; Monstad et al., 2011). For illustration, we focus on contraceptive choice in high-fertility context and assume that the probability that a woman ever adopts modern contraception is given by,

$$\begin{aligned} &\mathrm{P}(\text{woman adopts modern contraception}|x,\bar{y}) \\ &\quad = F(\alpha(\bar{y}-0.5)+\beta x+\gamma) \end{aligned} \qquad [1]$$

where α and β are positive parameters, γ represents individual characteristics, x is the level of family planning effort, F is the cumulative logistic function, and $\bar{y}$ is the proportion of women in the population who use modern contraception in the reference period. Hence, the social utility term $\alpha\ (\bar{y}-0.5)$ captures the dependence of a woman's contraceptive choice on the fertility behavior in her network, where we assume for the sake of simplicity that this network includes all members of the population. The model implies that social effects are absent in a population in which half of the members use modern contraception and the other half do not. If the proportion of contraceptive users exceeds (is below) 0.5 then the social network increases (decreases) the probability of using contraception. This simple model already reveals that the aggregate properties of fertility dynamics in the presence of

Figure 1 Implications of social networks for population dynamics. In the left-hand panel, social networks exert a relatively weak influence on individual contraceptive decisions ($\alpha = 3$), while in the right-hand panel the social network effect is relatively strong ($\alpha = 6$).

social interaction are distinct from the fertility dynamics in a purely individualistic model. In particular, the relevance of social interaction arises from three factors: social multiplier effects, multiple equilibria, and dense versus sparse networks.

Social Multiplier Effects

Social interaction implies the presence of multiplier effects, which change how the fertility level adjusts to changes in family planning programs. An increase in family planning effort x, for instance, increases the probability of choosing modern contraception in two distinct ways (Figure 1). The direct effect reflects the increase in the propensity to choose modern contraception while holding the population prevalence $\bar{y}$ constant. However, because the increased level of x affects all community members, the prevalence of modern contraception in the population tends to increase as well. This change in the community has a feedback or social multiplier effect on individual behavior in future periods via the social utility term in eqn [1]. This means that the total change in the prevalence of family planning exceeds the direct effect. The left-hand panel of Figure 1 shows how this total effect is composed of a direct effect and an indirect effect through social interaction. The interaction in social networks thus enhances the changes in contraceptive behavior that follow changes in family planning efforts or other socioeconomic changes.

Multiple Equilibria

Many formal fertility models assume that there is only one aggregate fertility level, denoted as 'equilibrium,' associated with any given level of socioeconomic conditions. When the interdependence of fertility decisions in social networks is sufficiently strong, however, multiple equilibria can emerge (right-hand panel of Figure 1). This possibility of there being multiple equilibria is relevant because in this case a population can be 'stuck' at a low level of contraceptive use, even though a second equilibrium exists with a higher level of contraceptive use and higher individual utility levels. In this case, increases in the policy level x (or other socioeconomic changes) can induce a transition from the low-contraceptive use to the high-contraceptive use equilibrium. These transitions between equilibria are often thought to occur at a rapid pace, resulting in significant changes in fertility behavior within a relatively short space of time. Moreover, both the high- and low-contraceptive use equilibria are stable, so that a transitory increase in the family planning effort can yield sustainable long-term changes in fertility levels.

Populations With Dense versus Sparse Networks

An important question in diffusion models is whether 'more' interaction in networks always leads to larger multiplier effects and more rapid diffusion. It can be shown that already in simple models such as eqn [1], social networks can be status-quo enforcing: the long-term effect associated with changes in the program effort can decrease with an increase in parameter α, which reflects the importance of the network influences in individual fertility decisions. The changes in contraceptive use resulting from changes in the program effort can therefore be smaller for very densely knit societies than for more sparse societies.

Fertility Change: Quantum and Tempo

John Bongaarts, The Population Council, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The 'quantum' and 'tempo' dimensions of fertility usually refer, respectively, to the average number of births per woman during the reproductive years and the average age at childbearing. These measures can be estimated for cohorts of women who have completed their childbearing years, as well as for specific time periods. Unfortunately, quantum measures of period fertility (e.g., the total fertility rate) can be distorted, because its quantum and tempo dimensions interact. Assessment of period fertility levels and trends therefore should include adjustments to remove tempo distortions caused by changes in the timing of childbearing.

The 'quantum' and 'tempo' dimensions of fertility usually refer, respectively, to the average number of births per woman during the reproductive years and the average age at childbearing (Ryder, 1980; Pressat, 1985). Using standard demographic methods these measures can be calculated for birth cohorts of women who have completed their childbearing years, as well as for specific time periods. More generally, the term 'quantum' can refer to the average numbers of births that have occurred in a group of women who have experienced a common event, such as marriage, or its measurement can be limited to births of a certain order, such as first births. Similarly, the term 'tempo' can refer to the average time elapsed between a birth and a specific preceding event (e.g., marriage) or its measurement can be limited to births of a certain order.

Estimation of the quantum and tempo of childbearing for a cohort of women is straightforward provided the required data are available and accurate. These variables quantify key dimensions of a cohort's reproductive history but they have the considerable disadvantage of representing past experience: women currently aged 50 did most of their childbearing two to three decades ago when they were in their 20s and early 30s. Trends in cohort measures therefore do not reflect current conditions, and they are not often used to monitor recent developments because fertility can change substantially in a short period of time.

An alternative quantum measure, the period total fertility rate (PTFR), is used far more widely as an indicator of current fertility. It is defined as the average number of births a woman would have if she were to live through her reproductive years (ages 15–49) and bear children at each age at the rates observed in a particular year or period. It is a hypothetical measure because no real group of women has experienced or will necessarily experience these particular rates. The advantage of the PTFR is that it gives up-to-date information on levels and trends in fertility. The PTFR is a quantum indicator of period fertility, and the mean of the age-specific fertility schedule is a tempo measure.

The simplicity and wide availability of the PTFR have contributed to a neglect of some deficiencies in this fertility indicator. The demographic literature on the measurement of fertility includes a number of criticisms of the PTFR (Ní Bhrolcháin, 1992). The most important of these is the distortion of the PTFR that occurs when the timing of childbearing changes. During years in which women delay childbearing, period fertility rates are depressed relative to cohort fertility; in years when childbearing is accelerated, period fertility is raised (Hajnal, 1947; Ryder, 1956, 1964, 1980, 1983). The quantum and tempo dimensions of period fertility interact.

To demonstrate how these tempo distortions operate, it is helpful to examine a set of simple illustrations as presented in Figure 1. In these hypothetical illustrations, every woman is assumed to have exactly one birth so that the cohort total fertility rate equals one for all cohorts, and these births are assumed to take place at exactly the same age within each cohort. Figure 1(a) depicts the reference situation in which this age is set at exactly 20 years. Since there are no tempo effects, period fertility as measured by the PTFR is also constant and equal to one birth per woman. Assume next that the age at childbirth is raised by 1 year starting at time T, as shown in Figure 1(b). In this case, women who would have given birth at age 20 immediately following T have to delay their childbearing for a year until they reach their 21st birthday. As a consequence, no births occur during the year between T and $T+1$ and the PTFR then equals 0. In other words, 1 year's worth of births is lost because the mean age at childbearing increased by 1 year. In reality, the mean age at childbearing rarely changes suddenly and rapidly. A more realistic situation is summarized in Figure 1(c), which illustrates the effect of a slow rise in the age at childbearing. Starting at time T, successive cohorts delay childbearing so that the mean age at first birth rises linearly from 20 to 21 years over a 10-year period from T to $T+10$. In this case, the PTFR drops from 1 to 0.9 at time T, remains at 0.9 from T to $T+10$, and finally returns to 1 after time T. The PTFR is distorted by 10% or 0.1 birth per woman during the interval T to $T+10$. Over the 10-year period, 1 year's worth of fertility is lost from the PTFR as a result of a 1-year increase in the mean age at childbearing. Conversely, as shown in Figure 1(d), if the mean age at first birth declines linearly from 20 to 19 years over the same period of 10 years, the PTFR rises from 1 to 1.1 at time T, remains at 1.1 from T to $T+10$, and returns to 1 birth per woman after T. Bongaarts and Feeney (1998, 2006) present a fuller discussion of these effects.

The existence of timing distortions is readily documented when the age at childbearing is declining significantly. In that case, implausible results are often obtained for the

Figure 1 (a), (b) Hypothetical patterns of childbearing, with and without tempo effects. (c), (d) Fertility impact of changes in age at childbearing.

birth-order components of the PTFR, computed as the sum over age of the period-specific fertility rates of the second kind by age and birth order. For example, the component for births of order one ($PTFR_1$) equals the average number of first births women would have by age 50 if they were to bear first births at the age-specific rates of the second kind observed in a given year or period. In most years during the late 1940s and early 1950s, the $PTFR_1$ in the US exceeded 1 (Whelpton, 1954), a fact which seems to imply that women had more than one first birth on average. This is impossible and these $PTFR_1$ estimates must therefore be reinterpreted. The main explanation of why $PTFR_1$ exceeded 1 during the baby-boom years is that the age at childbearing declined, resulting in a temporary inflation of the PTFR and its additive birth-order components:

$$\mathrm{PTFR} = \sum_n \mathrm{PTFR}_n \qquad [1]$$

A detailed analysis of the effects of variations in the childbearing tempo on period fertility indicators was undertaken by Ryder in a series of influential papers (Ryder, 1956, 1964, 1980, 1983). Ryder proposed 'translation' equations to calculate the period fertility measures from corresponding cohort measures when the timing of cohort fertility is changing. These procedures have not found wide acceptance for two main reasons. First, in his work on the translation issue, Ryder assumes that the tempo and quantum of cohort fertility are the determinants of the PTFR and other period fertility measures. However, extensive empirical analysis of this issue has demonstrated that this is not the case (Ní Bhrolcháin, 1992). Period effects are clearly the prime source of variation in fertility rates, and the completed fertility of cohorts is largely determined by the period fertility rates during the cohort's reproductive years, rather than the other way around. Second, the two dimensions of aggregate cohort fertility – quantum and tempo – are not independent in practice. When cohorts reduce their fertility, they do this primarily by reducing childbearing at higher birth orders. As a result, the mean age at childbearing for all births to the cohort declines even if the timing of individual births does not change. In other words, a decline in the cohort quantum can lead to changes in the cohort's mean age at childbearing

that do not cause tempo distortions. Such distortions only occur if the mean ages at births of specific orders rise or fall. Ignoring this effect – as Ryder does in much of his writing – therefore gives biased results except when cohort fertility is constant. Fortunately, this second problem can be solved by analyzing fertility trends separately for each birth order rather than for overall fertility.

A procedure for removing tempo effects from the PTFR was proposed by Bongaarts and Feeney (1998). The approach is an outgrowth of Ryder's original translation equation. The above objections to Ryder's approach are addressed by assuming that fertility is only affected by period effects, and by applying adjustments separately to the birth-order components (PTFR_n) of the total fertility rate rather than to the total fertility rate itself. Under these conditions, it is possible to estimate a tempo-free total fertility rate in any given year (or period) from the conventional PTFR_n at each birth order n with the formula

$$\mathrm{PTFR}'_n = \mathrm{PTFR}_n/(1 - m_n) \qquad [2]$$

where PTFR_n is the observed total fertility rate component for birth order n, PTFR'_n is the tempo-free total fertility rate component for birth order n, and m_n is the annual *change* in the mean age of the age-specific fertility schedule for birth order n. Dividing the observed total fertility rate by $(1–m_n)$ at any given birth order n, produces an estimate of the total fertility rate that would have been observed if there had been no change in the timing of childbearing. Adding up results for the various birth orders gives the overall tempo-free total fertility rate.

$$\mathrm{PTFR}' = \sum_n \mathrm{PTFR}'_n \qquad [3]$$

The PTFR′ equals the distortion-free quantum component of the PTFR, and the difference PTFR′–PTFR equals the tempo distortion.

According to this argument, an annual increase of one-tenth of a year in the mean age at childbearing ($m_n = 0.1$) reduces the PTFR_n by 10% below its tempo-free level, because $\mathrm{PTFR}_n = 0.9\ \mathrm{PTFR}'_n$. Similarly, an annual decline in the mean age at a rate of just 0.1 years per year ($m_n = -0.1$) inflates the PTFR_n by 10%. Clearly, rather modest changes in the timing of childbearing at any birth order can produce substantial changes in observed fertility.

The above simple formula for removing tempo distortions assumes that the shape of the age-specific period fertility rates at each birth order does not change over time. Kohler and Philipov (2001) have suggested a more general equation that incorporates variance effects. Their formula reduces to the simpler version presented here when the shape of the fertility schedule is invariant. Further discussion of different tempo adjustment procedures can be found in Bongaarts and Sobotka (2011).

The existence of tempo distortions of period fertility measures has recently become an important issue in contemporary developed countries. In most of these societies, fertility has dropped well below the replacement level. If future fertility remains at these low levels, populations will decline in size and age rapidly. The fact that ages at childbearing have been rising quite rapidly since the 1970s implies that the PTFRs of these countries contain a tempo distortion. Sobotka (2004) estimates the tempo effects for many posttransitional societies in the late 1990s and finds downward distortions ranging up to 0.55 births per woman in the Czech Republic. In several countries the tempo effect is the primary reason why the PTFR is below the replacement level.

Assessment of fertility levels and trends should include an analysis of the tempo effects because the conventional PTFR gives a misleading estimate of the actual rate of childbearing when the age at childbearing is changing. This is the case in many posttransitional populations. Childbearing is being delayed and women are actually bearing more children than is indicated by the observed PTFRs. This distortion in the PTFR will continue for as long as the mean age at childbearing rises, but once the deferment ends the distortion is removed, and the PTFR will then rise unless there are offsetting declines in the quantum component of period fertility. This is in fact the main reason why the PTFR has risen in the decade up to 2008 in many European countries (Bongaarts and Sobotka, 2011).

Fertility of Single and Cohabiting Women

Lawrence L Wu, New York University, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article provides an overview of current theory and empirical research on the fertility of single or cohabiting parents, with particular emphasis on research in the fields of demography, economics, history, and sociology. Topics covered include: historical shifts in usage concerning the terms employed to refer to these behaviors; measurement issues that arise in the study of nonmarital fertility; demographic trends; functionalist, historical, and policy literatures; empirical research to date on the socioeconomic determinants, including within-country and cross-national variation in the association between nonmarital fertility and socioeconomically disadvantage; consequences for women and children; and the continuing conceptual and theoretical challenges posed by the study of nonmarital fertility.

Historically, fertility outside of formal marriage has been referred to variously as bastardy, illegitimacy, or out of wedlock childbearing, with such terms connoting the inferior status of children born in such circumstances. More recently, the use of these terms has declined, in part because they presume an answer to the question of whether 'inferior status' is a necessary consequence of being born to an unmarried woman or whether some or all of the disadvantage typically accompanying such a birth might stem from other causes. Thus, terms such as nonmarital fertility or childbearing by single or cohabiting parents, which carry more neutral connotations, have seen increasing usage.

Measurement

The measurement of nonmarital fertility requires knowledge of at least two demographic statuses – fertility and marriage – and ideally others – whether a birth occurs within or outside of a cohabiting union. The first-order issue of identifying births that occur within or outside of formal marriage would appear to be a straightforward matter given sufficiently detailed data. Still, it is useful to identify potential inconsistencies across alternative definitions of nonmarital fertility, for example, 'the fertility of single or cohabiting women' versus 'childbearing to unwed parents.' Consider a birth conceived within a marital union in which the father dies before the child is born. Viewed one way, the child was conceived to married parents; viewed another way, the mother was single at birth by virtue of the death of her spouse. Similar issues arise for legitimated births or births to separated parents. In the latter case, because the birth occurs prior to the dissolution of a couples' formal marital union, one might view it as a marital birth. However, the child may have been conceived to the woman and a man other than her husband, either before or after marital separation; thus, another definition might classify such a birth as nonmarital. Note, furthermore, that the period between separation and divorce can be lengthy, with the timing of a formal divorce decree often a response to various factors, including the outcome (e.g., childbearing) under study. Consequently, some researchers have adopted an operational definition that shifts emphasis from formal to *de facto* marital status, thus including as nonmarital those births that occur between separation – marking the informal but behavioral dissolution of a marriage – and divorce – marking the formal dissolution of a marriage.

As a general accounting principle, one might suppose that the number of births to males and females should, in the aggregate, be identical, as when data are available from official birth registers. However, this principle need not hold under some definitions of nonmarital fertility (e.g., when both parents are married, but not to one another) given the types of data typically available to the analyst. Moreover, comparisons of survey and registration data often reveal that marriage and fertility data supplied by male respondents are markedly inferior in quality to those from female respondents, particularly with respect to male nonmarital fertility (Joyner et al., 2012). One consequence has been that there has been far less empirical research on male nonmarital fertility (for exceptions, see, e.g., Barber, 2001; Huang et al., 2005; Hofferth and Goldscheider, 2010; Carlson et al., 2013; Edin and Nelson, 2013). Although such an emphasis is often sensible, in that childrearing responsibilities continue to fall most heavily on women, it has nevertheless produced an asymmetry in research findings.

Additional measurement issues arise when attempting to distinguish between births to cohabiting couples versus those that occur in neither a marital nor cohabiting union. It is sometimes difficult to determine whether or when a cohabiting union has begun or ended, and both contemporaneous and retrospective reports of cohabitation may contain systematic biases (Teitler et al., 2006). These issues have led some to argue that cohabitation might be better conceptualized not as a discrete status but rather in terms of a continuum capturing the extent to which a couple might be said to coreside. Nevertheless, estimates from alternative data sources are often in substantial agreement, providing evidence, albeit of an indirect nature, suggesting that female survey respondents can provide reasonably accurate reports on their union status at birth, even retrospectively.

Demographic Trends

Nonmarital fertility has increased substantially in recent decades in both Europe and the United States. In the United

States, official statistics suggest that as of 2012, more than two in five births (40.7%) were to unmarried women, a level roughly four times higher than that in 1970, at which time one in nine births (10.7%) were to unmarried women. Estimates of cohort trends in the United States likewise reveal monotonic increases in various components of nonmarital fertility (Wu, 2008). Period levels and trends in much of Europe mirror those in the United States. As of the late 1990s, more than every third birth occurred outside of marriage in France, the United Kingdom, Finland, and East Germany, and roughly every second birth was nonmarital in the Scandinavian countries of Iceland, Sweden, Norway, and Denmark (Kiernan, 2001).

Nonmarital, as compared to marital, fertility, continues to occur at relatively early ages in the United States. Increases in women's age at first marriage have necessarily implied corresponding increases in women's ages at a marital first birth; by contrast, period trends in women's ages at a nonmarital first birth between 1970 and the mid-1990s were far more modest (Wu et al., 2001). Thus, differences in the age structure of nonmarital and marital fertility remain substantial in the United States. For example, in 2010, 88.2% of all births to teen women were nonmarital; for women 20–24, nearly two of three births (64.1%) were nonmarital. U.S. nonmarital fertility has also increased substantially among women over 19 years of age. In 1970, one half of all nonmarital births were to teenage women, but by the early 1990s, nonmarital births to women of 20 years of age and older accounted for more than two-thirds of all nonmarital births. These period trends have also been accompanied by marked declines in the likelihood of marriage in certain social and demographic groups, leading some to argue that observed trends result from a decline in male 'marriageability' stemming from a deterioration in men's economic circumstances (Wilson, 1987; Oppenheimer, 1994, 2003) or in declines in the relative wages of males and females (Schultz, 1994; Willis and Haaga, 1996; Willis, 1999; Moffitt, 2001). By contrast, two studies present evidence suggesting that period increases in nonmarital fertility from the late 1960s to the early 1980s (Akerlof et al., 1996) or cohort trends in premarital first births for women born during baby boom (England et al., 2013) were due primarily to decreases in the tendency to respond to a premarital conception by marrying before the birth, leading the former to interpret these trends as a behavioral response to a changing contraceptive regime (e.g., the birth control pill and abortion legalization) and the latter to question hypotheses concerning male marriageability.

Nonmarital fertility in the United States continues to differ substantially by race and ethnicity. In 2010, nonmarital births comprised nearly 3 in 10 of all births to non-Hispanic white women (29.0%), over half of all births to Hispanic women (53.4%), and nearly three of four of all births to non-Hispanic black women (72.5%). These differences also extend to births in cohabiting unions. Births to cohabiting white women have risen sharply in the last two decades (Bumpass and Lu, 2000; Raley, 2001; Kennedy and Bumpass, 2008), accounting for virtually all of the observed increase in nonmarital fertility. A continuing puzzle, however, is that births to cohabiting black women account for a far smaller proportion of nonmarital black births. Fewer than one out of five of recent nonmarital births occurred to cohabiting black women and, over time, births within cohabiting unions have constituted a declining fraction of nonmarital births to black women (Wu et al., 2001).

Nonmarital fertility in the United States and Europe differs in several important respects. The overlap between teen and nonmarital fertility, characteristic historically of the United States, is largely absent in the European context. In addition, births within stable cohabiting unions constitute a far larger fraction of European than of U.S. nonmarital births, with the overwhelming proportion of nonmarital births in Europe occurring within cohabitation (Kiernan, 2001). As a result, recent cohorts of U.S. children are likely to spend more years, on average, growing up without a father present in the child's household than are their European counterparts. Nonmarital fertility in the United States has also been linked to multipartner fertility, family diversity, and family complexity (Meyer et al., 2005; Wu and Li, 2005; Carlson and Furstenberg, 2006; Cherlin, 2010; Furstenberg, 2014). It is not clear if these patterns are distinct to the United States or if they also hold in Europe and elsewhere.

One might expect that the decoupling of both sexual activity and childbearing from marriage and the accompanying erosion of norms proscribing nonmarital fertility (Bumpass, 1990; Pagnini and Rindfuss, 1993; Cherlin, 2010; Smock and Greenland, 2010; Regnerus and Uecker, 2011; Murray, 2012) would imply that nonmarital fertility will have increasingly diffused beyond poor and disadvantaged segments of society to the nonpoor and more highly educated (Whitehead, 1993; Cherlin, 2001). The available empirical evidence is mixed on this point. The prevalence of cohabiting births in Europe and, in particular, Scandinavia has been interpreted by some as consistent with this view (Popenoe, 1996); however, Kiernan (2004) finds that cohabiting births are far more prevalent for the less educated compared to the more highly educated, a pattern that holds across all European countries Kiernan examined and which also holds in the United States and Great Britain, where nonmarital fertility continues to occur predominantly among those with less education and where there is accumulating evidence of diverging trends in the sociodemographic characteristics of married and unmarried mothers (Hoffman and Foster, 1997; Wu et al., 2001; Haveman et al., 2001; McLanahan, 2004; Murray, 2012).

Functionalist, Historical, and Policy Literature

The distinction between social and biological parenthood implicit in the discussion of measurement of nonmarital fertility was an explicit emphasis of early functionalist authors in anthropology and sociology (see, e.g., Malinowski, 1930; Davis, 1939). A classic statement due to Malinowski is:

> The most important moral and legal rule concerning the physiological state of kinship is that no child should be brought into the world without a man – and one man at that – assuming the role of sociological father, that is guardian and protector, the male link between the child and the rest of the community. I think that this generalization amounts to a universal sociological law, and as such I have called it … *The Principle of Legitimacy*. (pp. 137–38).

Accumulating empirical evidence of violations of this principle led Goode (1960) to argue that it was more likely to be followed or enforced when fathers were high in status, as when a father possessed substantial income or assets, or when his stake in the child was high.

By contrast, historians have often used nonmarital fertility as a rough empirical proxy for premarital or illicit sexual activity, while also emphasizing the ebbs and flows in both the incidence of 'bastardy' in different historical periods and the tenuous connection between levels of nonmarital fertility and the intensity of social or moral disapproval (Laslett et al., 1980; Stone, 1979). Moreover, while public and moral authorities typically viewed nonmarital childbearing as concrete evidence of fornication or adultery, real concern is argued by some to have centered around the financial burdens posed to the community by children born out of wedlock. Wells (1979), in particular, concludes that local authorities in colonial America were by and large "unwilling to punish children for the sins of their parents," noting, for example, that "both William Franklin, the last royal governor of New Jersey, and Alexander Hamilton were able to achieve political eminence … despite the fact that their parents were not legally married."

The question of whether the sins of parents should be visited on children remains highly relevant to contemporary policy debates. A continuing policy dilemma is that social and economic resources directed to children born outside of marriage also in effect provide assistance to parents – it is often difficult to target social policies and provisions in ways that benefit children but not parents. This concern has been less evident among policy-makers in Europe, with many European nations having had a longer and more generous tradition of social welfare provisions. It has, however, played a central role in U.S. policy debates, where concern that welfare programs such as Aid to Families with Dependent Children (AFDC) may have had the unintended consequence of increasing nonmarital births was a major factor in the dismantling of these programs in favor of those intended to discourage nonmarital childbearing.

The specific issue of whether more generous AFDC benefits increased nonmarital births in the United States spawned an extensive research literature. The available evidence, constructed largely from cross-sectional U.S. data (see Moffitt, 1998 for a review), finds support for such an association, with most researchers finding that this association is small in magnitude. However, a persistent puzzle generated by these cross-sectional findings is that they appear inconsistent with period trends in nonmarital births and welfare generosity, with nonmarital births increasing and the inflation-adjusted value of AFDC and other benefits falling in recent decades (Ellwood and Jencks, 2004). One possibility is that there is in fact no real inconsistency between the time series and cross-sectional evidence, in that falling AFDC benefits may have acted to reduce nonmarital births, but that other factors may have operated in the opposite direction to increase nonmarital births. Surprisingly little work has been done with respect to this issue, save for Moffitt (2001), who presents evidence in support of this possibility.

These issues were much in evidence when AFDC provisions in the U.S. for poor single mothers and their children were replaced in 1996 by a program entitled 'Temporary Assistance for Needy Families' (TANF), which imposed strict time limits on cash aid to poor single mothers and their children. Potential evidence that time limits did indeed discourage nonmarital fertility is at best mixed. On the one hand, trends in the period nonmarital fertility ratio, defined as the proportion of births to unmarried mothers relative to all births in a given calendar year, ceased increasing in the years immediately following the introduction of TANF; however, such evidence would also appear to suggest that such an effect was confined to a brief 3-year period, with increases in the nonmarital fertility ratio resuming in 2000. It is worth noting that the nonmarital fertility ratio (as well as more general period measures of overall fertility that combine marital and nonmarital births) appears to have been sensitive to economic conditions, with the nonmarital fertility ratio remaining essentially unchanged between 2008 and 2012 (the most recent year for which data were available), thus spanning a 4-year period that coincides with the beginning and aftermath of the serious economic recession of 2008.

Studies that have employed designs intended to better identify a causal effect of welfare reform have yielded mixed results to date. Two studies (Kaestner et al., 2003; Lopoo and DeLeire, 2006) report evidence suggesting a causal link between welfare reform and reductions in teen fertility, while two other studies (Horvath-Rose and Peters, 2001; Hao and Cherlin, 2004) report evidence inconsistent with any such causal link. Yet another study reports evidence suggesting no causal link between welfare reform and observed declines in welfare caseloads (Klerman and Haider, 2004).

Socioeconomic Determinants

A consistent finding in the U.S. literature (see, e.g., McLanahan and Sandefur, 1994) is that the risk of a nonmarital first birth is associated with family structure, with the standard finding being that these risks are higher for women who resided in a nonintact or single-mother family at some point during adolescence. This empirical association appears remarkably robust, for example, to adjustments for unmeasured factors shared by siblings (Powers and Hsueh, 1997) or the tendency for women with premarital first births to have initiated sexual activity slightly earlier than other women (Wu and Martin, 2009).

A difficulty with many of these studies is their reliance on a 'snapshot' of family structure, typically measured at 14 or 16 years of age, which makes problematic the interpretation of what exactly it is about family structure that may account for the higher observed risk of a nonmarital first birth. Somewhat surprisingly, evidence to date does not support widespread expectations concerning the intergenerational transmission of nonmarital childbearing – that being born outside of marriage raises the risk that a young woman will herself bear a child outside of marriage (Wu and Martinson, 1993; Wu, 1996; Haveman et al., 2001). Instead, what appears to be transmitted across generations is the propensity to bear a child at an early age (Barber, 2001; Haveman et al., 2001; Wu and Martin, 2009). Another consistent finding is that low-income and low educational attainments of parents appear substantially associated with premarital first birth

risks (Haveman and Wolfe, 1994; McLanahan and Sandefur, 1994; Wu, 1996; Ermisch, 2001). Four studies find that turbulent family environments, in the form of repeated changes in family structure, are associated with higher risks of a premarital first birth for females (Wu and Martinson, 1993; Haveman and Wolfe, 1994; Wu, 1996) or for males but not females (Hofferth and Goldscheider, 2010).

Consequences for Women and Children

Nonmarital childbearing is commonly thought to carry adverse consequences, both for the woman bearing the child and for the children born into such families. An early view capturing this sentiment (Campbell, 1968) held that:

> The girl who has an illegitimate child at the age of 16 suddenly has 90% of her life's script written for her. She will drop out of school; even if someone else in her family helps to take care of her baby, she will probably not be able to find a steady job that pays enough to provide for herself and her child; she may feel impelled to marry someone she might not otherwise have chosen. Her life choices are few, and most of them are bad.

Although this view remains highly influential in many respects, the research community has increasingly regarded it with substantial skepticism. Furstenberg et al. (1987) find substantial variability in the life course outcomes for women who began childbearing while in their teen years, many of whom had births while unmarried, leading many to question if a woman's life script is in fact '90% written' as a consequence of teen (and nonmarital) childbearing. Wu et al. (2001), using nationally representative U.S. data, document similar variability for women with nonmarital births, suggesting that the results of Furstenberg and colleagues may also hold for more recent cohorts of women. Another basis for skepticism is the realization by researchers that previous studies may have overstated the magnitude of the negative effects of teen childbearing. Indeed, a considerable controversy has arisen over whether teen childbearing might be held to have any causal relationship to the later social and economic disadvantages observed for teen mothers (see, e.g., Geronimus and Korenman, 1993; Grogger and Bronars, 1993; Hoffman et al. 1993a,b; Rosenzweig and Wolpin, 1995; Hotz et al., 2005; Lee, 2010; Stange, 2011).

Similar issues arise when evaluating findings from the extremely large empirical literature that has examined outcomes for children who resided at some point with a single parent in that this literature rarely distinguishes between whether such families were formed through divorce or nonmarital fertility (Seltzer, 2000). Thus, much of this literature is in fact silent on outcomes for children born to unmarried mothers, aside from documenting that these children are substantially more likely to grow up in poverty. As noted above, several studies find no empirical evidence in support of the transmission of nonmarital childbearing across generations. Korenman et al. (2001) find that the higher prevalence of unintended births among unmarried mothers relative to married mothers appears to account for little of the observed differential in parenting behaviors, infant health, or child development between marital and nonmarital births. Haveman et al. (2001) find that children born to unmarried mothers are significantly less likely to complete high school than children born to married parents.

The research literature has also been slow in providing evidence on the consequences of being born to cohabiting parents. One well-documented finding is that mean income is higher for married relative to cohabiting families and lowest in single-mother families, with these differences affecting the economic resources available to children residing in these families (see, e.g., Manning and Lichter, 1996; Carlson and Danziger, 1999; McLanahan, 2004; Manning and Brown, 2006). Empirical studies of Great Britain and the United States (Ermisch, 2001; Wu et al., 2001; Manning et al., 2004; Raley and Wildsmith, 2004; Wu and Musick, 2008) find that children born within a cohabiting union are far more likely to experience the loss of a parent – most typically the father – through the dissolution of their parent's union than are children born within marital unions. One study, comparing cohabitors who married before a first birth with cohabitors who married after a first birth, found no significant difference between these two groups in union stability following first birth, suggesting perhaps that decisions concerning marriage and childbearing may be made jointly by at least some cohabiting couples (Wu and Musick, 2008). Findings concerning the greater instability for children born to cohabiting versus married parents must also be weighed in light of evidence suggesting that this is far less true in continental Europe than in the United States or Great Britain (Kiernan, 2001, 2004). It is also worth emphasizing that what is observed – the presence or absence of a marital or cohabiting union – is but a crude proxy for the economic, social, and emotional commitments of the parents to the child, commitments which may, in turn, vary substantially over time.

Conceptual and Theoretical Challenges

Unlike much empirical research, theoretical work has taken seriously the 'two-sex' nature of nonmarital fertility – for example, how nonmarital fertility might respond to both men's and women's characteristics. Notable examples include Wilson's (1987) argument, reviewed above, concerning a dearth of 'marriageable' males in the U.S. black community and Willis' economic models of nonmarital fertility (Willis and Haaga, 1996; Willis, 1999), in which different distributions in the relative wages of men and women may produce behavioral equilibria in which men move from a pattern of high to low paternal investment in the children they father. Neal (2001) proposes a model that implies that the prevalence of nonmarital fertility can vary substantially if the choice set for women is expanded to consist not only of giving birth within or outside of marriage, as assumed by both Wilson and Willis, but also of the option of foregoing a birth entirely.

The study of nonmarital fertility poses other unusual challenges, both theoretically and empirically. One is that nonmarital fertility lies at the intersection of several joint (and potentially

endogenous) processes by which families are formed – relationships, cohabitation, marriage, and childbearing. A second challenge concerns the likely life course dynamics underlying nonmarital fertility. Empirical research is complicated by the fact that many key aspects relevant to this process are either unobserved or at best partially observed by the researcher, including the timing of initial (and ensuing frequency of) sexual activity, contraception among those who are sexually active, abortion, and how the resolution of a nonmarital pregnancy is regarded by the woman and by other relevant actors. A further challenge is that recent trends in nonmarital fertility may well reflect an evolving response by individuals to fundamental changes in the long-term contract represented by marriage, a contract that has itself changed in response to other social forces, including the near-universal levels of sexual activity and cohabitation prior to marriage, changes in the nature and levels of labor force participation of men and women, and continuing high levels of divorce and union instability (Seltzer, 2000; Lundberg, 2001; Cherlin, 2010; Furstenberg, 2014).

Abstract

This article provides a review of fertility research in advanced societies, where birth control is the default option. The central aim is to provide a comprehensive review that summarizes how contemporary research has explained ongoing and expected fertility changes across time and space. The core determinants of fertility are grouped according to the analytical level in which they operate. Determinants are positioned at the individual/couple level (micro-level), social networks (meso-level), and by cultural and institutional settings (macro-level). The focus is on both quantum and tempo of fertility.

Introduction

During the last two decades, research about fertility in advanced societies – societies in which birth control is the default option – has flourished.

Since the 1980s, an increasing number of European and Asian countries reached very low fertility levels (Caldwell and Schindlmayr, 2003) and virtually all advanced societies witnessed a 'postponement' transition (Kohler et al., 2002a). For this reason, the topic of low-fertility-dominated fertility research in advanced societies. During the late 2000s, a reversal of the fertility decline in most advanced countries – albeit with great heterogeneity – has drawn considerable attention (Goldstein et al., 2009; Myrskylä et al., 2009; OECD, 2011). Another emerging topic is the impact of economic uncertainty and the recent economic recession on fertility (Mills and Blossfeld, 2005; Sobotka et al., 2011).

In order to illustrate the state of fertility research and the main fertility theories, this article provides a contemporary review of research and delineation of the core determinants of fertility. Determinants are categorized according to the analytical level at which they operate. Specifically, three levels can be identified: the micro-level, that is, the individual and/or couple level; the meso-level, which encompasses social relationships and social networks (i.e., characteristics pertaining to the network of friends, coworkers, relatives, and/or the relationship that links them to the individual); and the macro-level, which refers to the cultural and institutional settings where individuals and couples are embedded.

While distinguishing the different analytical levels, the two main components of fertility will as well be taken into account: tempo (i.e., the timing of childbirth) and quantum (i.e., the total number of children). When examining tempo, it is known that OECD countries have witnessed a rising mean age at first birth since the 1970s, coupled with an increasing proportion of births among mothers at advanced ages, albeit with considerable country-level variation (Billari et al., 2007; Sobotka et al., 2010; Mills et al., 2011). This process is generally referred to as the postponement of childbearing, which is the central focus of tempo studies in fertility research. The emergence of a 'postponement transition' of higher ages at first birth is a core phenomenon that has emerged in the last decades (Kohler et al., 2002a; Billingsley, 2010).

Quantum is related to the number of children (including childlessness). While demographic transition theory had implied that the quantum of fertility would stabilize around the replacement level of around 2.1 children per woman (e.g., Bongaarts, 2002), during the last decades of the twentieth century, advanced societies witnessed low, or even the 'lowest-low' or 'ultra-low' fertility levels close to 1 (e.g., Kohler et al., 2002a; Frejka et al., 2010). The novelty of this phenomenon captivated demographers and raised the concerns of policy-makers about both the long-term demographic sustainability of their populations and concerns about the growing gap between desired and achieved fertility (Chesnais, 1996; Bongaarts, 2001; Goldstein et al., 2003; OECD, 2011). Just as there appeared to be a consensus that advanced societies would either remain at low fertility levels or reach even lower levels (e.g., Lutz et al., 2003), new research produced evidence demonstrating onset of a fertility reversal during the 2000s (Goldstein et al., 2009; Myrskylä et al., 2009; OECD, 2011).

The remainder of this article is structured as follows. The following section focuses on the determinants of fertility at the micro-level, followed by a section illustrating factors acting at the meso-level. The final section reviews fertility research at the macro-level.

Micro-Level Determinants of Fertility

Research at the micro-level focuses on the individual and/or couple decision-making process underlying the choice to have a child and investigates which circumstances affect decisions regarding the timing and number of children. Choices are often characterized as a rational response to uncertainty and/or as conformity to the prescribed 'sequencing' of life course events. A rich body of research has studied the link between life course circumstances and trajectories (mainly, partnership, education, employment, and economic conditions) and fertility behavior. Other research has instead focused on the role of social class and family, or origin, which in turn shapes an individual's values and preferences. A major obstacle in this line of research is the challenge to establish causality, or in other words, the ability to empirically determine whether these life course factors are actual determinants of fertility or whether certain life course factors and fertility behavior are simultaneously affected

by the presence of other common determinants (endogeneity or reverse causality).

Fertility Intentions

Many scholars have used fertility intentions as a proximate determinant for actual fertility behavior, examining which factors influence the formation, realization, and/or change in fertility intentions (e.g., Westoff and Ryder, 1977; Schoen et al., 1999; Quesnel-Vallée and Morgan, 2003; Berrington, 2004; Liefbroer, 2009; Philipov, 2009; Spéder and Kapitány, 2009). Others have identified the systematic gap between intended and actual fertility as one of the causes of low fertility (Morgan and Taylor, 2006), since it reveals an 'unmet need' for children (Liefbroer, 2009).

Next to critical approaches that downplay the explanatory power of intentions and less individual-specific measures such as ideal family size (e.g., Westoff and Ryder, 1977; Quesnel-Vallée and Morgan, 2003), other studies argue that intentions are effective predictors of actual fertility (Schoen et al., 1999; Berrington, 2004). The majority of these latter studies draw upon the social psychological literature, often employing the Theory of Planned Behavior (TPB) (Ajzen, 1991). According to the TPB, intentions are the culmination of a combination of three antecedents: (1) attitudes (i.e., perceived costs and benefits); (2) subjective norms (e.g., influence of close friends and relatives); and (3) perceived control over behavior (i.e., extent to which behavior is perceived as subject to control by the individual).

Partner and Partnership

Changes in partnership dynamics experienced in the past decades across advanced societies has been linked to the postponement of parenthood. A growing number of studies have shown a parallel tendency to delay union formation and parenthood (Corijn and Klijzing, 2001), an increased frequency to have several partners before the first child (Wu and Schimmele, 2005), and a rise in unmarried cohabitation, which has been associated with a later age at entry marriage (Bumpass et al., 1991; Mills, 2004), if not a 'retreat from marriage' (Gibson-Davis et al., 2005).

Partnership status (i.e., cohabitation and marriage) (Hobcraft and Kiernan, 1995; Philipov et al., 2006; Testa, 2006) as well as a variety of other characteristics of both partners or of the couple have likewise been found to influence childbearing (e.g., Thomson et al., 1990; Corijn et al., 1996; Thomson and Hoem, 1998; Jansen and Liefbroer, 2006).

With the growth of more unstable relationships and higher levels of separation and divorce, another relevant topic has been the influence of union (in)stability and/or low relationship quality on childbearing. Although causal links are complex and there are important feedback mechanisms (Waite and Lillard, 1991), the existing literature provides evidence for two opposing mechanisms. Some studies find a negative relationship between low quality/instability of partnership and having children (Thornton, 1978; Myers, 1997). On the other hand, Friedman et al. (1994) argue that union instability leads to earlier childbearing since children are seen as a source of uncertainty reduction and thereby operates to enhance marital solidarity.

Gendered Division of Labor

Another important factor influencing fertility is the gendered division of domestic labor of couples within the household. Contemporary work builds on McDonald's (2000a,b) gendered fertility theory, which argues that very low fertility is the result of a hiatus of sustained gender inequity in family-oriented social institutions. Esping-Andersen (2009), also drawing on the work by the economist Goldin (2006), sees low fertility as a consequence of the 'incompleteness' of the revolution that transformed women's roles.

Stepfamily Fertility

The increase in unstable and multiple unions has also brought a growth in the study of stepfamily fertility. This body of research demonstrates that partners who already have children from previous unions are more likely to have a child together, often considered as a union commitment effect (e.g., Vikat et al., 1999; Buber and Prskawetz, 2000; Stewart, 2002; Prskawetz et al., 2003). Given that one child is enough to indicate commitment in a partnership, multiple relationships and subsequent partnerships might significantly contribute to total fertility.

Income, Education, and Human Capital

Socioeconomic circumstances of individuals have also been studied as determinants of fertility quantum and timing. Income (and wages in particular) has attracted considerable research interest in economics. Depending on the economic model that is adopted, the effect might be different. The family economics approach, pioneered by Becker (1960), maintains that individuals obtain direct pleasure from having and raising children, and from their well-being. Children, and possibly their quality level, thus resemble a consumption good in the utility function of their parents. While the initial formulation of this theory implies a positive link between income and number of children, the large body of literature that followed focused on a negative relationship between income and fertility, emphasizing two aspects. First approach focuses on the quality–quantity tradeoff, proposed by Becker and Lewis (1973) and Willis (1973). Here the argument is that an increase in income may lead to fewer children. This is attributed to the fact that parents with a higher income value children's quality, but a focus on higher-quality raises the cost of having (and raising) children, thereby potentially reducing fertility levels. A second approach focuses on the opportunity cost of having children, especially for women. Since raising children requires parental (and especially maternal) time, fertility is more costly for higher-income mothers, who are therefore expected to have fewer children (e.g., Kravdal, 1992). This is related to the literature that demonstrates a 'motherhood wage penalty,' with postponement of motherhood providing considerable earnings returns for higher educated women or those in professional occupations (Van Bavel, 2010; Begall and Mills, 2012). Others have extended Becker's static model by setting up dynamic economic models of the optimal timing of first birth (mostly focusing on women), based on the minimization of opportunity costs of childbearing, 'wage penalty,' and income loss (Happel et al., 1984; Cigno and Ermisch,

1989). They theorized and demonstrated that the higher the accumulation of human capital during education or the higher the returns to education, the later the transition to motherhood.

A similar approach has been adopted by the rich body literature that focuses on the relationship between education and labor market trajectories and the timing of first birth. The argument is that due to the accumulation of human capital, women with higher levels of education are more likely to pursue careers and increase their earning power. This likewise releases them from the pressure to get married and have a child for economic reasons. As the opportunity costs of childbearing and childrearing increase with human capital, highly educated women are more likely to postpone marriage and births. An important critique of this approach has been put forth by Oppenheimer (1994), who argues that highly educated women are more likely to find partners who are highly educated as well. This in turn operates as an incentive for women (because they can further pool economic resources) to enter into a union and subsequently have children once they complete their education. Although higher educated women have their first child later than their lower educated counterparts, some studies (Sobotka, 2004; Kravdal and Rindfuss, 2008) have highlighted that the higher educated are also more likely to recuperate at a later age.

The results linking education to fertility are, however, mixed, with recent empirical results instead showing a nonrelevant association between education and fertility (e.g., Skirbekk, 2008).

Other researchers have instead focused on the importance of educational enrollment, as opposed to the highest achieved level of education. Here findings show that individuals who are still enrolled in education are at a lower risk of having a child, likely attributed to the presence of a 'sequencing norm' of first finishing education, followed by parenthood (Hoem, 1986; Blossfeld and Huinink, 1991). Others have extended this research to also examine the importance of the educational field of study in relation to either socialization or self-selection effects into later occupations, which in turn impact fertility (e.g., Van Bavel, 2010; Begall and Mills, 2012).

Economic and Employment Uncertainty

Further, mostly sociological studies focus on the importance of employment status and, particularly, economic uncertainty on fertility outcomes. Theories of (largely economic) uncertainty are reminiscent of Easterlin's (1976) theory of economic deprivation, which posits that in historical periods of general economic uncertainty and rising unemployment, the tendency to marry and have children appears to diminish. This also relates to Oppenheimer's (1988, 2003) work on the impact of uncertainty in social and economic roles on the timing of family transitions. An increasing number of studies link economic uncertainty – often in the form of unemployment and precarious labor market situations – to the postponement of parenthood (Mills and Blossfeld, 2005; Kreyenfeld, 2010).

Fertility Preferences

An individual's fertility decisions are shaped by his or her own preferences, which several authors emphasize, are shaped early in an individual's life. Catherine Hakim's Preference Theory (2003) positions the heterogeneity of women's lifestyle preferences at the heart of fertility (and labor market) choices in advanced societies. Hakim assumes that lifestyle preferences are rather constant across the life course, with three main types: career oriented, family oriented, and those oriented toward combining work and family. These lifestyle preferences are seen as the main driver – with policies required that take into account this heterogeneity.

Research on preferences for the sex composition of children shows an effect of sex preferences on the probability to have more children (Andersson et al., 2006; Mills and Begall, 2010), albeit with considerable variation across countries (Hank and Kohler, 2000).

Intergenerational Transmission of Values and Behavior

The similarities of fertility histories across successive generations has also been a core area of research, focusing mainly on the stable result of a positive correlation between the number of siblings and number of own children (Thornton, 1980; Anderton et al., 1987; Axinn et al., 1994; Murphy and Wang, 2001) or between the age at first birth of parents and that of their children (Rijken and Liefbroer, 2009). The majority of studies concerning tempo focus on teenage motherhood, demonstrating that having had a young mother increases the risk of having a child at a young age (Furstenberg et al., 1990; Manlove, 1997). Within this body of literature, the intergenerational transmission of behavior is considered to be driven by intra-familial socialization processes that occur during childhood and adolescence (Thornton, 1980; Axinn et al., 1994; Murphy and Wang, 2001). The assumption is that parents transmit family values, preferences, and attitudes, as well as contraceptive knowledge.

Biodemography of Fertility

Next to socialization mechanisms, biological and genetic factors have also been used to explain intergenerational similarities in fertility preferences and behavior (Wachter and Bulatao, 2003). A series of studies have linked biological and genetic components to fertility behavior (Kohler et al., 1999, 2002a; Kohler and Rodgers, 2003). This body of research focuses on studying the interplay between fertility, environment, and genetic makeup of individuals and demonstrates that differences in the genetic composition of individuals affect their fertility outcomes and fertility-related behavior. There is also growing evidence that genetic variance changes over time and across educational levels, meaning that the importance of social norms and individual decision-making change across time (Kohler et al., 1999, 2002a; Kohler and Rodgers, 2003). The biology of fertility has also been revolutionized by the rapid diffusion of various types of assisted reproductive technologies (ART).

Socioeconomic Status and Cultural Context of Family of Origin

A related stream of research investigates the effect of the socioeconomic and cultural context of the family of origin on an individual's age at childbearing and fertility quantum decisions. Some studies have shown that there is a negative relationship between parents' educational level (especially father's education) and age at first birth (Blossfeld and

Huinink, 1991; Billari, 2001) as well as the number of children (Murphy and Wang, 2001; Rijken and Liefbroer, 2009). A negative relationship has also been found between parents' financial situation (i.e., job status) and (expected) number of children (Thornton, 1980; Murphy and Wang, 2001) and age at first birth (Rijken and Liefbroer, 2009). These findings suggest that in higher educated and high-status families, other goals beyond family formation are more easily transmitted, together with aspirations for material goods (Easterlin, 1969). Therefore, if consumption aspirations are high, parenthood will be reduced or at least postponed. For the opposite reason, parents' religiosity is positively associated with their children's fertility (Rijken and Liefbroer, 2009).

Meso-Level Determinants of Fertility

In recent years, increasing attention has been devoted to developing and applying theories that take into account the fact that individuals are positioned as social actors who make decisions and act while embedded in a web of social relationships with kin and peers. While some studies focus on the role of interpersonal interactions in shaping an individual's fertility decisionmaking, others investigate how the place of residence is associated with reproductive choices. Finally, another body of research looks at the social network as a source of social capital in the form of emotional and material aid. However, the acknowledgment of the importance of the social network in explaining observed fertility patterns has not as of yet been coupled with a convincing body of empirical research. The central reason rests with the lack of suitable data and the difficulty to model and properly identify social interaction effects. The social context or other individual-level factors common among individuals can also explain similarities in behavior (e.g., same timing of childbearing), and the social network may be chosen according to desired behaviors and changes over time.

Social Interaction

The impact of social interaction on fertility choices has received considerable attention (e.g., Bongaarts and Watkins, 1996; Montgomery and Casterline, 1996). This literature has predominately focused on the diffusion of contraceptive methods in developing countries (Kohler et al., 2001) and identified two channels via which social interaction takes place. The first is social learning, or how individuals gain knowledge from others, and the second is social influence, which is how consensus in peer groups constrains attitudes and behavior.

In advanced societies, research illustrates that personal network contacts such as coworkers, siblings, or friends are pivotal in shaping both fertility timing as well as quantum decisions (Bernardi et al., 2007; Axinn et al., 1994; Manski and Mayshar, 2003; Lyngstad and Prskawetz, 2010; Balbo and Mills, 2011; Balbo, 2012).

Place of Residence

Several studies document fertility differences by place of residence along several lines. First, fertility continues to vary across regions (Caltabiano, 2008; Kertzer et al., 2009). According to Kulu (2011), differences in desired family size explain fertility differentials between small towns and rural areas on the one hand, and urban areas on the other. Second, within urban areas, suburbs are consistently found to have higher fertility (Kulu et al., 2009), with single-family households associated with higher fertility (Kulu and Vikat, 2007). These differentials persist when controlling for the socioeconomic composition of areas (Kulu and Boyle, 2009), suggesting that contextual effects shape fertility decisions. However, the association between the place of residence and fertility choices raises causality concerns, since the relation might be spurious and the effect can work in both directions.

Social Capital

The body of research focusing on the social network as a source of social capital (Bühler and Philipov, 2005; Philipov et al., 2006) stems largely from sociological theory (Lin et al., 2001; Flap and Völker, 2004). Social capital is defined as the resources that individuals have access to via personal relationships and can include goods, as well as information, money, capacity to work, influence, power, or active help (Granovetter, 1973; Bourdieu, 1986; Coleman, 1988). Building on previous sociological applications (Granovetter, 1973; Bourdieu, 1986; Lin et al., 2001; Flap and Völker, 2004), some demographic studies have demonstrated how social capital (or the lack thereof), next to economic and cultural resources, shapes fertility decision-making (e.g., Schoen et al., 1997; Astone et al., 1999; Bühler and Philipov, 2005). This research looks at long-term, stable and trusting relationships (e.g., family members, grandparents, close friends, or relatives) that can provide the individual or the couple with fertility-relevant supportive resources.

The majority of existing studies on social capital as a determinant of (low) fertility has focused on ex-communist Eastern European countries. This region has undergone a period of extreme socioeconomic uncertainty after the end of the Soviet Union. In such a context, supportive network relationships and resources play a crucial role in an individual's fertility decision making (Bühler and Philipov, 2005). Consistent with this argument, several empirical studies demonstrate that the greater the social capital, the higher the probability to have a child (Philipov et al., 2006; Bühler and Fratczak, 2007) and to have the child sooner (Bühler and Philipov, 2005; Philipov et al., 2006).

The US literature focuses on the support that kin provide to mothers, including childcare and help with raising children, especially for single mothers – here kin are seen as providing 'safety nets.' This is particularly significant given the high rates of partnership instability and single parenthood and is a strong focus of the 'Fragile Families' study (Harknett et al., 2001). Harknett and Knab (2007) find that multipartnered fertility, through the difficulties of maintaining kin networks, lowers the financial, housing, and childcare support to mothers.

Macro-Level Determinants of Fertility

A vast literature focuses on how the cultural and institutional setting in which individuals and couples are embedded affects their fertility decision making. Here an 'economy versus culture' dichotomy can be identified (Billari, 2004). While several

studies investigate how economic trends, social policies, institutional constraints, and welfare regimes influence fertility tempo and quantum, other contributions focus on the influence of values, attitudes, and culture in reproductive behavior. Moreover, next to these two broad approaches, other macro-level studies look at the role of contraceptive technologies in fertility dynamics. Once again, the main challenge of this literature rests on how to deal with endogeneity and causality issues. Difficulties in disentangling the impact of policies from other observable or unobservable factors have often frustrated the effort to uncover policy effects on fertility. It is difficult to separate the impact of any specific policy from the broad range of policy instruments that potentially influence fertility, and it is problematic to empirically establish whether a specific policy was successful due to the temporal lag between policy initiation and take-up. Moreover policies might be endogenous, in that they may not only impact fertility and induce change, but are often a reaction to changes in fertility and an integral feature of these changes.

Economic Trends

Period effects of economic trends on fertility are usually investigated by linking the total fertility rate (TFR, which represents the number of children that would be born to a woman if she were to live to the end of her childbearing years and bear children in accordance with current age-specific fertility rates) to macroeconomic indicators (e.g., GDP and unemployment rate). The relationship between TFR and GDP is ambiguous. Several studies (e.g., Martin, 2004) find a pro-cyclical relationship between economic growth and fertility in the developed world. Fertility decline during economic recessions are seen as a result of childbearing postponement, especially of first births, which can later be largely compensated during times of economic prosperity. Similar arguments can be found in Kohler et al. (2002a), Mills and Blossfeld (2005) and Sobotka et al. (2010), who maintain that an economic downturn brings about uncertainties that in turn, lead to postponement. Other studies, however, find contrasting results. Butz and Ward (1979) suggest that economic upswings bring about the increased employment of women, making children more expensive during times of economic prosperity. Therefore, fertility trends are likely to be countercyclical (Macunovich, 1996). The negative relationship between economic growth and postponement also seems to be contradicted by some recent studies (Billingsley, 2010; Aassve et al., 2006).

A related approach that has recently received great attention is the one that explains fertility patterns and cross-country fertility differences in terms of socioeconomic development. Myrskylä et al. (2009) provide evidence for a fundamental change in the well-established negative relationship between fertility and development. They find that while low and medium levels of the Human Development Index (HDI) are associated with persistent low fertility, higher HDI levels seem to promote fertility, reversing the declining pattern.

(Un)employment Trends

Economic uncertainty has also been studied by examining the effects of unemployment trends on the TFR. Findings consistently showed a negative association: the higher the unemployment, the lower the quantum of fertility (Macunovich, 1996) or the higher the postponement, which was found for first and second births (Adserà, 2010, 2011).

Adopting a complementary approach, other studies focus on the relationship between female labor force participation (LFP) and TFR, showing that in OECD countries, this association has changed from negative (where countries with higher LFP had lower TFR) to positive during the 1980s (Pampel, 2001; Ahn and Mira, 2002). It is, however, challenging to assess whether this implies a change in the causal relationship between the two variables. Mishra et al. (2010), engaging in a macro-econometric analysis aimed at ruling out endogeneity in order to unravel causation, find that causality runs from changes in fertility (TFR) to changes in LFP.

Another approach on the effects of economic trends has been developed by Easterlin (1961, 1968). According to Easterlin, cyclical changes in fertility are mainly due to fluctuations in birth rates and cohort size. Members of larger cohorts face more competition and thereby reduced economic opportunities, leading to lower fertility.

Policy Measures

A second stream of research has studied the impact of policy measures (e.g., labour-market, fiscal, family, or housing policies) on the timing of parenthood, as well as on fertility quantum. There is mixed evidence regarding the effectiveness of social policies on fertility (Gauthier, 2007; Hoem, 2008). Gauthier (2007) argues that their effects, although small, seem to affect the timing of fertility rather than the number of children.

A large number of studies investigate the effects of childcare provision on fertility. Most of the empirical research shows mixed findings. While some studies find that regions with poor childcare coverage have higher fertility (e.g., Rosen, 2004), others find that public availability of childcare has a positive effect on fertility (Rindfuss et al., 2010). Social security systems, and the reform in social security, have been discussed as determinants of fertility (Cigno and Rosati, 1992). The relevance of social security for fertility choices is also linked to the idea that children may provide security in old age, also in advanced societies (Rendall and Bahchieva, 1998).

Similar to economic factors, with which they are closely interrelated (Hoem and Hoem, 1997), the effect of family policies varies according to the institutional context and individual-level determinants.

Welfare Regimes

Building on the work of Esping-Andersen (1990, 1999), numerous scholars have explained cross-country differences in fertility and life course patterns by linking them to different institutional constellations. As described in Mills and Blossfeld (2005), who link different welfare regimes to fertility postponement, differences between welfare regimes manifest themselves in the priority of: (1) active employment-sustaining labor market policies (i.e., the commitment to full employment); (2) welfare-sustaining employment exit policies (i.e., support for those who are outside of the labor market such as

youth, unemployed, ill, poor, family care workers, and pensioners); (3) the scope and generosity of family allowances and services (i.e., maternity/paternity leave and childcare); and (4) the share of the public sector in the labor force. This constellation of policies in turn impacts the safety net that individuals can draw upon. Employment regulations and family-related services (e.g., childcare and leave) enable or constrain decision making about entry into parenthood or having additional children.

Defamilialized regimes, where the households' welfare and caring responsibilities are largely supported by the welfare state (and not the family), such as Nordic socio-democratic countries, or market provision (Anglo-Saxon liberal market regimes), enable higher fertility. Conversely, familistic states (Conservative and especially Southern European regimes), where the majority of the economic and caring responsibilities rest on the family, where institutions also support a traditional division of the domestic labor (i.e., the so-called male-breadwinner model), constrain fertility, resulting in lower fertility levels.

Value and Attitude Changes

This stream of research largely stems from the 'Second Demographic Transition' (SDT), developed by Lesthaeghe and van de Kaa (1986) to interpret demographic changes in industrialized societies. According to this theory, ideational changes, that mainly consist of the rejection of institutional control, accentuation of individual autonomy, and the rise of self-realization needs are the driving forces of new family arrangements and behaviors, among which are fertility postponement, reduced number of children, or childlessness, that have developed since the 1960s. As highlighted by Van de Kaa (1997), such ideational changes may occur in different periods and at a different intensity across diverse areas. The SDT framework has been used as an alternative (Lesthaeghe, 1983) or complementary explanation (Billingsley, 2010), next to economic cycle effects, to fertility quantum variations.

Other studies focus on the impact of changing social norms on fertility. Several researchers have documented the relevance of age deadlines for childbearing (i.e., ages after which it is not socially acceptable to become a parent) (Liefbroer and Billari, 2010). Billari et al. (2011) illustrate that age deadlines are positively associated with the prevalence of ART in a given country.

Historical and Cultural Continuities

Some studies identify historical and cultural continuities – or path dependency – as the roots of present fertility behaviors, reaching similar conclusions to that of Esping-Andersen (Reher, 1998; Dalla Zuanna, 2001). However, this literature, by strongly emphasizing the importance of cultural background, assumes that culture has shaped institutional settings (Pfau-Effinger, 1999).

This body of research can be distinguished along East–West and North–South divides. The East–West divide in Europe, running along an imaginary line connecting Trieste and St. Petersburg, was first noticed by Hajnal (1965). On the West side of the 'Hajnal line,' areas were characterized by late and not universal marriage, whereas to the East of the line, marriage was early and widespread. Historical continuities are then assumed to explain why birth happen earlier to the East of the Hajnal line. The North–South divide, first elaborated by Reher (1998), considers the strength of intergenerational family ties: while Southern countries are characterized by strong family ties, Northern areas generally have weak family ties. The main argument is that systems characterized by strong kinship and intergenerational relationship (e.g., Southern European familistic countries) are those where couples have lower fertility (Dalla Zuanna, 2001) and young people delay the transition to adulthood, in turn implying a postponement of childbearing (Billari, 2004). It is essential to note that familistic regimes, both from an institutional as well as cultural point of view, are not 'per se' detrimental to fertility. It is rather the interaction of these systems with the recent increased female status in the educational and labor market system and lack of institutional support to combine work and family that is the root cause of low fertility (Mills et al., 2008).

Studies on immigrants, linking fertility in the place of origin to the behavior of individuals in a 'destination' country have also shown the relevance of cultural continuities (Fernández and Fogli, 2006, 2009), with continuity in behavior. Nevertheless, migrants often show behavior that converges to their place of destination, demonstrating that adaptation prevails on selectivity (Kulu, 2005).

Contraceptive and Reproductive Technologies

Fertility differentials at the macro-level are not only explained by 'economy' and 'culture.' Researchers have widely studied the crucial role of the 'contraceptive revolution' on fertility quantum (e.g., Frejka, 2008) and fertility postponement (Sobotka, 2004). The spread of modern contraception, and especially the pill, has radically changed the nature of the fertility decision making and contributed to the reduction in the number of children and the postponement of childbearing (Goldin, 2006). On the other hand, the development of assisted reproductive technology (ART) seems to challenge the biological limits to postponement (Billari et al., 2007; Leridon, 2008).

Abstract

The embodied-capital theory generalizes existing life history theory by treating the processes of growth, development, and maintenance as investments in stocks of somatic or embodied capital. The theory provides a means of understanding relationships between economic behavior, social behavior, and demographic traits such as fertility and survival. The approach sheds light on the long-term evolution of human life histories (including slow development, long life span, and menopause) and social structure (including high levels of parental investment and intergenerational transfers). It also provides an explanation of the demographic transition to low fertility that has accompanied modernization. This article reviews data from traditional small-scale societies and modern nations bearing on the theory, and addresses the changing roles of physiological, psychological, and cultural mechanisms that underlie fertility behavior in traditional and modern contexts.

The goal of this article is to provide an introduction to the embodied-capital theory of life history evolution and the empirical research upon which it is based. The embodied-capital theory generalizes existing life history theory in evolutionary biology by treating the processes of growth, development, and maintenance as investments in stocks of somatic or embodied capital (see Kaplan, 1996, 1997 and Kaplan et al., 2000 for more complete treatments). In a physical sense, embodied capital is organized somatic tissue – muscles, digestive organs, brains, etc. In a functional sense, embodied capital includes strength, immune function, coordination, skill, knowledge, and other abilities. Since such stocks tend to depreciate with time in response to metabolic activity (e.g., the production of free radicals and mutations associated with mitosis) and aging, allocations to maintenance can also be seen as investments in embodied capital. The logic of embodied capital theory provides a means for understanding the coevolution of the age schedules of fertility, mortality, and kin investment, and thus a range of phenomenon from the evolution of life span and menopause to modern demographic transition. In this article, the general theory is introduced and then applied to human hunting and gathering societies, which characterized most of our species' evolutionary history. This framework is then used to develop models of modern fertility behavior as the result of an interaction between historically novel conditions and the evolved psychological, cultural, and physiological mechanisms governing human parental investment and fertility.

The Embodied-Capital Theory of Life History Evolution

Hominids lived as hunter-gatherers for the vast majority of their evolutionary history (more than 2 million years). Agriculture originated only 10 000 years ago and has been practiced by the majority of the world's population for just two or three millennia, a relatively brief period of time for selection to act. The shift to a fully mercantile, highly urbanized economy with competitive wage–labor markets and a vast array of consumer goods since the mid-nineteenth century is completely novel. Since natural selection is a historical process, humans should be well adapted to the foraging lifestyle, but there is no reason to expect that they will respond adaptively (in the sense of maximizing reproductive fitness) to today's novel circumstances (see Kaplan et al., 1995a; Goodman et al., 2012 for evidence that modern fertility behavior does not maximize fitness). Therefore, an evolutionary explanation of human fertility and parental investment has three requirements: it must be consistent with our general understanding of evolution by natural selection; it must explain the behavior of humans living under traditional hunting and gathering conditions characteristic of our evolutionary history with adaptive models; and it must be able to predict the pattern of modern responses to novel conditions.

Our approach to satisfying these requirements has been to follow a four-step procedure (Kaplan, 1996; Kaplan and Lancaster, 2000). The first step is to develop a model of natural selection on fertility and parental investment for organisms in general. The second step is to apply that model to the specific selection pressures acting on human hunter-gatherers. The third step is to develop a model of the proximate physiological, psychological, and cultural mechanisms produced by selection and how they would interact to determine fertility and parental investment behavior. The fourth step is to generate predictive models of how those mechanisms would respond to conditions currently prevailing in the world. The theory is both ecological and psychological, integrating socioeconomic influences with a theory of mind to identify the processes by which salient features of the social and physical environment relate to people's reproductive and parenting behavior across diverse social, cultural, economic, and ecological contexts.

The Action of Natural Selection on Fertility and Parental Investment

Natural selection acts on variability in the traits of individual organisms within populations. Traits (and the genes that code

for those traits) whose *average* effects on those who possess them act to maximize their 'inclusive fitness' will tend to increase in frequency relative to other traits. *Inclusive fitness* includes effects both on the reproductive success of the individual bearing the gene and on other individuals, related by common descent, who also bear the gene. For example, selection on genes affecting alarm calls in response to predators depends both on their effects on the reproductive fitness of the caller – who may risk a greater threat of predation – and on relatives bearing those genes – whose lives may be saved by the call.

Fertility is the most direct contributor to an organism's fitness (i.e., the number of descendants it produces). In fact, all other fitness components, such as mortality, only affect fitness through their effects on fertility (for example, mortality rates affect fitness by affecting the probability of living to the next reproductive event). All else constant, any increase in fertility increases an organism's fitness. However, there are two trade-offs affecting natural selection on fertility.

The first is the trade off between present and future reproduction. By growing, an organism can increase its energy-capture rates in the future and thus increase its future fertility. For this reason, organisms exhibiting determinant growth typically have a juvenile phase in which fertility is zero until they reach a size at which some allocation to reproduction increases fitness more than growth. Similarly, among organisms that engage in repeated bouts of reproduction (humans included), some energy during the reproductive phase is diverted away from reproduction and allocated to maintenance so that it can live to reproduce again. Natural selection on age of first reproduction and on the adult reproductive rate is expected to maximize total allocations of energy to reproduction over the life course, and it depends on ecological factors, such as mortality rates and the effects of body size on energy capture and vulnerability to predation (Werner, 1986; Charnov, 1993; Kaplan and Robson, 2009).

The second trade-off is between quantity and quality of offspring, where quality is a function of parental investment in offspring and reflects its ability to survive and reproduce. In general, natural selection on offspring number and investment per offspring is expected to maximize the number of offspring that survive to reproduce themselves (Smith and Fretwell, 1974). Ecological factors, such as food supply, disease, and predation rates, also affect the optimal fertility rates and optimal expenditures on offspring.

Virtually, all complex organisms exhibit flexibility in both the age at first reproduction and fertility rates. Natural selection has resulted in physiological and psychological mechanisms by which individuals adjust fertility onset and fertility rates in relation to changing environmental conditions. For example, plants often exhibit many 1000-fold variations in fertility rates in relation to yearly and seasonal variations in rainfall and other environmental factors. Extensive research on many bird species has shown that this phenotypic plasticity tracks fitness fairly well (see Godfray et al., 1991; Bennett and Owens, 2002 for reviews). Birds under variable conditions adjust clutch sizes in ways that tend to maximize the number of surviving young produced during the life course. The pervasiveness of adaptive phenotypic plasticity in fertility among nonhumans suggests that humans are also likely to possess adaptations to adjust fertility onset and fertility rates in relation to changing environmental conditions.

The Embodied-Capital Theory and Its Application to Fertility and Parental Investment among Traditional Humans

The embodied-capital theory treats the present–future reproduction trade-off in terms of optimal investments in own embodied capital versus reproduction, and the quantity–quality trade-off in terms of investments in the embodied capital of offspring versus number produced. Models based on the theory allow us to address problems that have not been addressed with standard life history models. First, an exclusive focus on physical growth per se is an impoverished way of understanding human development. The large human brain, a stock of embodied capital, supports a great deal of learning and knowledge acquisition during both the juvenile and adult periods. Second, parental investment among humans affects not only survival to adulthood, but also the adult socioeconomic status of offspring. This is true not only in modern societies, but traditional hunter-gatherers also exhibit high levels of parental investment in offspring (Kaplan et al., 2000).

These models of investment in embodied capital have produced some fundamental results. At their most expansive, the models establish a general theory for the evolution of senescence and aging, through consideration of the costs and benefits of the developing and maintaining the quantity and quality of embodied capital over the life span (Kaplan and Robson, 2009). Of central interest here, they have also showed that investments in embodied capital affecting adult income or energy capture coevolve with investments affecting mortality and longevity. The longer the time spent growing and learning prior to reproducing, the more natural selection favors investments in staying alive to reap the benefits of those investments. Similarly, any investments that produce increased energy-capture rates later in life select for additional investments to reach those older ages. The converse is also true. Ecological features or investments that increase the probability of survival to older ages also produce selection for greater investments in income-related embodied capital (Kaplan and Robson, 2002). These coevolutionary effects have been particularly important in human life history evolution.

The human adaptation is broad and flexible, in one sense, and very narrow and specialized, in another. It is broad in the sense that as hunter-gatherers, humans have existed successfully in virtually all of the world's major habitats. This has entailed eating a very wide variety of foods, both plant and animal, both within and among environments. It also has entailed a great deal of flexibility in the contributions of different age and sex classes of individuals. The relative contributions of men and women to food production vary from group to group, as do production profiles by age.

The human adaptation is narrow and specialized in that it is based on extremely high investments in brain tissue and learning. In every environment, human foragers consume the largest, highest quality, and most difficult-to-acquire foods, using techniques that take years to learn (Kaplan et al., 2000).

This adaptation has profound effects on fertility, mortality, and wealth flows. Compared with other primates and mammals, there are at least four distinctive characteristics of human life histories: (1) an exceptionally long life span; (2) an extended period of juvenile dependence, resulting in families with multiple dependent children of different ages; (3) support of reproduction by older postreproductive individuals; and (4) male support of reproduction through the provisioning of females and their offspring.

The coevolution of brains, learning and life histories is evident in **Figure 1**. This figure plots net expected cumulative productivity by age (cumulating the probability of being alive at each age times the net productivity at that age) for human hunter-gatherers and wild-living chimpanzees, averaging over available data from different groups (see Kaplan et al., 2000 for details). The long human training period is evident when the troughs in the human and chimpanzee curves are compared. Humans are not net producers until about age of 18–20 years, but are very productive as adults, whereas chimpanzees begin to produce as much as they consume by about age of 5 years and are much less productive as adults. In fact, peak production rates for both human males and females do not occur until the mid-thirties for the most difficult-to-acquire resources. Humans also have an expected adult life span of about 40 years when they become net producers, whereas chimpanzees have an expected adult life span (beginning at about age of 13 years) of 14 years. The dashed line is a hypothetical cross of human production profiles with chimpanzee survival rates. It shows that the human production profile would not be viable with chimpanzee survival rates, because expected lifetime net production would be negative. The human adaptation depends on about 20 years of parental support and a long life span to recoup the investments in learning.

This body of theory can also account for the cessation of fertility in the form of menopause in terms of four principal considerations. First, oocytes and the other reproductive physiology constitute stocks of somatic capital, which are developed and maintained at a cost before and during the reproductive career. Second, childbearing itself entails direct costs in terms of maternal mortality and maternal depletion. Third, continued reproduction often trades off with economic productivity, which we know to be high at advanced ages in both sexes in traditional human societies. Fourth, humans' emphasis on quality over quantity of oocytes and offspring compared to other primates interact with these costs to determine a typical age schedule of reproductive activity and cessation, which precedes general somatic aging. In effect, selection has favored the programmed shutdown of reproduction as oocyte quality decreases with age in order to realize the gains to late-age production and economic transfers to young. These downward transfers support both the reproduction and embodied capital development of family members. Empirically, there is evidence that people adjust transfers on the basis of generation, need, and genetic kinship (Hooper, 2011), as would be predicted theoretically on the basis of inclusive fitness theory. Where monogamous unions predominate in old age, many men in traditional societies experience behavioral menopause at the same time as their wife, and fulfill considerable economic roles for close kin and family.

'The major demographic transition separating our species from apes was thus a shift to low mortality, an increased life span, a long dependent development period, a large commitment to learning and intelligence, menopause, and an age profile of production shifted toward older ages with downward wealth flows across generations.'

Figure 1 Cumulative expected net caloric production by age: humans and chimpanzees.

Ecology and the Proximate Mechanisms Governing Fertility and Parental Investment

The mortality and production profiles discussed above have direct implications for fertility regulation. Since human parents and grandparents provision children, it is likely that natural selection would have produced mechanisms by which fertility could respond to the number of children parents could afford to raise at any given time. Figure 2 presents a conceptual model of the evolved mechanisms of fertility regulation in humans and its responsiveness to physical, biological, and social conditions (*socioecology*). The figure depicts two classes of socioecological factors, one affecting survival and the other embodied capital, and three domains of evolved responses, psychology and culture, behavior, and reproductive physiology. The pathways in solid black refer to the traditional hunting and gathering lifeway, which we consider first. The pathways in striped gray include additional factors and causal pathways existing under modern conditions.

Traditional Foraging Societies

There are two main causal pathways regulating fertility that are both related to the energy constraints in provisioning offspring, one involving breastfeeding and the other involving the age profiles of work and food distribution. Natural selection on the timing and rate of weaning should reflect a balance between quantity effects (favoring earlier weaning) and quality effects on survival and growth of offspring (favoring later weaning). Socioecological conditions, such as the availability of easy-to-digest weaning foods and disease threats, are likely to impact the relationship between age at weaning and survival. Similarly, infant condition is likely to be individually variable and differentially affected by weaning. We expect that natural

Figure 2 A mode of fertility determinants under traditional and modern conditions. Pathways in solid black are predominant under conditions of traditional natural fertility, while those in striped gray are predominant under modern economic and technological circumstances.

selection has acted on both infant and maternal psychology to make them responsive to those variable conditions. For example, sickly infants may be more demanding of the breast, and larger and healthier babies more interested in weaning foods. In the human case, maternal perceptions regarding breastfeeding are not only guided by her individual experience and sensitivity to her infant's condition, but also by the cumulative experience of her group, as reflected in cultural conventions and ideas about proper breastfeeding practices. Thus, there is likely an interaction between maternal and infant psychological processes in determining the length and timing of breastfeeding. The evolved reproductive physiology in the hypothalamic–pituitary axis translates this pattern of breastfeeding into differing degrees of fecundity.

The second causal pathway is due to the additional energy constraints involved in provisioning children. The age/sex profile of work and productivity determines the total energy available for consumption. Given some age profile of food distribution and of mortality, the fertility rate must be constrained so that energy consumed does not exceed energy produced. The longer children are provisioned and the greater proportion of their food needs subsidized by parents and grandparents, the lower the reproductive rate that can be supported with a given adult income.

Natural selection is therefore expected to act both on psychological abilities to assess the short- and long-term costs and benefits of different activity profiles and on fertility regulation so that energy flows are balanced. One fundamental trade-off with respect to activity profiles is between present and future production (Kaplan, 1996; Bock, 2002). If children engage in easy-to-perform foraging activities, such as fruit collection, this will provide immediate caloric benefits and lower the parental subsidy required. However, time allocation to those activities detracts from time spent learning more difficult activities, such as hunting and extractive foraging. During the learning phase, those activities produce very less food, but generate high rates of production in the future. Another fundamental trade-off is between production and mortality risks, since foraging exposes people to predation, accidents, and getting lost. This suggests that parental psychology should be responsive to age-specific mortality rates, how these rates are affected by alternative activity profiles, and their short- and long-term consequences for production/productivity.

There is a growing body of evidence supporting the view that people in foraging societies are sensitive to these trade-offs and adjust behavior accordingly. In a seminal series of papers, Blurton Jones and coworkers (Blurton Jones et al., 1994a,b; Hawkes et al., 1995) show that !Kung hunter-gatherer parents consciously assess foraging risks to children and that differences between Kung and Hadza children's productivity are due to features of the local ecology related to ease of resource extraction and dangers associated with productive tasks. Bock (1995, 2002), in a study of forager/agropastoralists in Botswana, shows that the age profiles of children's activity budgets reflect immediate skill and strength requirements as well as opportunities to learn. In all foraging societies for which data are available, people are aware of the many years of learning required to become a competent hunter and young men are provisioned while they learn those skills (Kaplan et al., 2000; Walker et al., 2002; Gurven et al., 2006).

These time-allocation decisions affect fertility through maternal energetics. In addition to breastfeeding effects, fecundity responds to women's net energy flows. Seasonal changes on food intake (Bailey et al., 1992), net energy expenditure (Hurtado and Hill, 1987), and weight (Bailey et al., 1992; Tracer, 1996; Kaplan et al., in press) all have been shown to predict fecundity, as do individual differences among women (Hill and Hurtado, 1996). These results are reviewed in Ellison's (2001) classic synthesis.

To summarize, in this model fertility is determined by the interaction of individual psychology and cumulative cultural knowledge, beliefs and practices, behavior, and reproductive physiology. These domains necessarily coevolved by natural selection, producing an ability to respond to ecological variability in mortality regimes and payoffs to parental subsidization of skill acquisition. The connection between psychology and fertility is indirect in that psychology adjusts parental investment (through productive behavior, wealth flows, and breastfeeding) and reproductive physiology translates parental investment decisions into fertility. The key to this system is that maximizing lifetime expected resource production through the optimal allocation of activities and wealth flows will tend also to maximize fitness when all wealth is in the form of food and extra food translates into higher fertility.

Fertility under Modernizing Conditions

In **Figure 2**, the additional socioecological factors and causal pathways proposed to result in fertility transition are shown in striped gray. Our proposal is that this fertility regime results from the interaction of new socioecological conditions with the psychological processes governing parental investment and wealth flows, evolved in response to the hunting and gathering lifeway. The two critical new factors are the existence of extrasomatic capital and changes in the payoffs to embodied capital, especially in the form of education.

Extrasomatic physical capital, such as land and money, is stored and invested in children in the form of inheritance and parental support for education. Unlike the traditional case where all wealth is embodied, there is no guarantee that a wealth-maximizing psychology will maximize fitness, because much wealth may never be converted into offspring and remain stored in other physical forms. In addition, perceptions about the optimal amount of physical capital to transfer to offspring may require lower fertility than the energy-based physiology of women will produce, stimulating a desire to control unwanted fertility through other means.

Changes in the payoffs to embodied capital occur for two reasons. Changes in the technology of production stimulating the development of education-based labor markets have led to very high returns on parental investments in children's education. There are multiple inputs into the production of education-based embodied capital. Parental time inputs prepare children for school and affect their progress in school. Variation in the quality of those inputs, perhaps based on parental education, may predict both levels of parental investment and fertility. Teachers, educational

materials, and the quality of student preparation all affect rates of learning (Card and Krueger, 1992).

Changing medical technology and public health efforts greatly reduced mortality rates for all age groups. Increased survival rates during the period of parental investment increase the expected costs per child born, favoring further increases in offspring quality (Kaplan, 1996). Increased survival during the adult period increases the expected years of return of educational investments, further increasing the incentive to invest in children's education.

It will be especially productive to investigate the public and private dynamics involved in this process. Increased private interest in education may have inspired more public investment in education. The quality of public education, in turn, increased the rate of return on private investments in education. Similarly, increased private interest in health (perhaps inspired, in part, by increased investment in education) also stimulated increased public investment in health. This, in turn, increased payoffs to educational investments.

The increased importance of physical capital and education appear to result in desired fertility levels far below those which would be produced by evolved physiology alone. Throughout most of the world, fertility is now regulated by the use of birth-control technology and/or controlled exposure to sex, as part of what is often a consciously determined childbearing plan. In response to the increased payoffs to investments in education and the expected costs of those investments, parents determine the number of children they can afford to raise, given their wealth. The low mortality rates also allow parents to plan reproduction at the outset, because the number of children born accurately predicts the number of children that will be raised to adulthood. Reproductive physiology affects fertility in the present in that it sets the broad limits within which a childbearing plan can be realized, and may actually lower fertility when plans include significant delays to first reproduction (Kaplan et al., 2001).

A great deal of further research is necessary, however, before we can understand why these changes in socioecology have resulted in such low levels of fertility and high levels of parental investment and wealth consumption. It does not appear that people are simply maximizing family wealth because net wealth of families would be maximized by higher fertility than is currently observed. It is also clear that people are not maximizing personal consumption; in that case, they would have no children. One possible hypothesis is that the social dynamics of small groups in hunting and gathering economies resulted in greater fitness for those of higher social standing and selected for a psychology in which relative social position of self and offspring is valued highly. Such a psychology would also emerge if people judged the well-being of themselves and their children based upon the wealth and consumption of others. This psychology may have been fitness maximizing under traditional conditions. If relative, as opposed to absolute, wealth and social standing guide human decisions regarding wealth flows, parental investment, and fertility, it is possible that 'run-away' consumption and investment in children's education result from the interaction of this psychology and modern education-based labor markets and consumption possibilities.

Implications of Embodied-Capital Theory for Understanding Current Fertility Transitions

Embodied-capital theory links several existing theories of demographic transition and, in so doing, provides a new perspective on each one. It rationalizes the shift from natural fertility to parity-specific fertility in terms of a changing quality/quantity trade-off, as a transition from high fertility/low parental investment to low fertility/high parental investment. It also shows why the shift to lower mortality rates can lead to lower fertility, but for reasons that are very different from what traditional demographic-transition theory proposes. According to the latter, lower mortality precedes and drives lower fertility, because fewer children are required to maintain the population equilibrium and cultural ideologies evolve to maintain population equilibrium. According to the present view, mortality rates are but one important factor in the overall rate of return on investments in embodied capital.

This model can further serve to organize research on fertility transitions, with the fundamental expectation that exogenous factors affecting the rate of return on parental investment in the embodied capital of offspring will predict the timing of fertility decline and its distribution within populations. Understanding these dynamics may provide insights into the course of fertility reduction and its variation across countries and among individuals within countries. For example, most studies of predemographic-transition societies show that there is a positive association between wealth and fertility (Borgerhoff Mulder, 1992). There is some evidence for a negative relationship during the demographic transition (Kaplan et al., 1995a; Vining, 1986) and no relationship after the transition is complete (Kaplan et al., 1995a). It may be that only the wealthy can take advantage of high levels of investment in children's embodied capital when there are few schools and limited public expenditures on health and education. The process of demographic transition may progress through different sectors of the society as more and more people can take advantage of increased rates of return due to changes in the economy and changes in public investments. These same dynamics, in combination with international transfers of educational and health technology, may also explain the national differences in the timing of fertility reduction.

Understanding these dynamics also requires an understanding of how people process the mix of information derived from direct assessment, observation of others, and cultural guidelines. The rapid change in economics of production, public education, and public health may lead people to reject existing cultural models, look for new models, and assess costs and benefits of alternative courses of action more consciously on the basis of direct experience. International family planning programs present one set of new models, promoting lower fertility and greater investment in children's education. When those models are consistent with individual assessments of costs and benefits, the direction of change is clear. It is less clear, however, how people will respond to family planning messages in the short and long run if the payoffs to investment in embodied capital are low, either because schools are poor or because employment opportunities for educated people are limited (as appears to be the case in many sub-Saharan African countries).

Conclusion

According to embodied-capital theory, fertility and parental investment behavior result from the interaction of exogenous conditions with an evolved response system shaped by natural selection. In addition, a distinctive feature of the learning-intensive nature of human psychology is that information about the environment and guidelines for behavior are obtained through cultural sources as well as through direct personal assessment (Bock, 1999, 2001). We still know very little about the mix of physiological, psychological, and cultural processes underlying decisions regarding wealth flows, educational investments and consumption patterns, or how those processes relate to fertility decisions. Understanding the complex interplay of exogenous conditions, cultural forces, and evolved response systems in the determination of family structure and fertility presents a formidable challenge, but one that promises great rewards.

Fertility Theory: Theory of Intergenerational Wealth Flows

Abstract

Caldwell's theory of wealth flows explains fertility decline as a rational decision by parents based on the direction of intergenerational transfers. In high-fertility contexts, this theory proposes that children produce more than they consume and therefore provide net wealth to parents. In contrast, in low-fertility contexts, parents invest more in children, resulting in children being a net economic cost. Empirical tests of this hypothesis have not found evidence to show that children are net providers to parents in high-fertility contexts. A weaker prediction of the model, that when children are more expensive, parents desire fewer of them, has been supported.

Introduction

Caldwell's wealth flows theory (1976a, 1980, 2005) was developed to explain the demographic transition from high to low-fertility regimes. The theory, which focuses on the flow of resources between generations, has stimulated a large body of empirical research, and has been modified in response to those empirical findings and in response to worldwide decreases in fertility that have occurred since it was first proposed. In addition, during the last two decades, intergenerational wealth flows has become an increasing focus of research by evolutionary anthropologists who apply ecological models to explain both parental investment and fertility jointly.

This article reviews Caldwell's original proposal, its extensions, and the empirical results it has stimulated. It then provides an overview of new approaches being applied by evolutionary anthropologists, concluding with a synthesis of the current state of our knowledge and new directions for research.

Wealth Flows Theory

Caldwell's theory of wealth flows proposes that fertility behavior is rational decision-making by parents. The theory predicts that in high-fertility contexts, parental wealth is increased by having more children. In those contexts, children work at young ages (Caldwell, 1976b) and care for elderly or sick parents in adulthood (Caldwell, 1966). Caldwell (1976a) argues that children's work and support in old age together result in contributions of children to parents being greater than those from parents to children over their joint life spans.

In addition to the quantifiable help children provide, large families can be beneficial through their increased political power (especially adult children married into other families). Large families also provide insurance against risk; if, for example, an individual family has crop failure, they can call on extended family members for support (Caldwell, 1981; Caldwell et al., 1985). In such circumstances, children are a source of wealth for parents and therefore parents choose to have as many children as they can.

A corollary prediction is that parents will choose to have lower fertility when children no longer provide wealth to parents and the transfers of wealth instead flow from parents to children. The demographic transition from high-fertility to low-fertility regimes begins as values and behavioral norms prioritize individual accomplishments, freedom, and well-being over contribution to the extended family. As individuals shift their emotional connection to their spouse and children over extended kin, they begin increasing investments in children, making them more expensive, leading parents to desire fewer or no children. This transition occurred first in Western Europe, the United States, and Australia as schooling became universal, transmitting those values.

Caldwell (1980) argues that the primary determinant of the onset of the fertility transition is universal schooling's effect on the family social structure. While education increases the cost of childbearing because of lost production while children are at school, the cost of school fees and uniforms, and the demand by children for consumer goods, it also changes the way society views childhood. As societies incorporate western ideology of nuclear families from mass education and mass media, couples begin to prioritize their spouse and children over the extended family. It is this change that leads to fertility decline.

Schooling makes it clear that society views children as the future and children need to be valued as more than simply child laborers. Usually the first generation of mass schooling is enough to initiate fertility decline, as parents recognize that they will not receive more from children than they will have to invest in them. In societies where the extended family structure can be maintained even with a large number of children attending school, fertility decline may not occur until those children who attended school become parents.

Different researchers have defined levels of education in different ways, such as literacy rates or the percentage of individuals educated, but Caldwell argues that it is mass education (or universal schooling) that really matters. It is not until all (or the vast majority) of children are educated that the values surrounding childhood and nuclear families change, and it is the education of women that is particularly important in forcing a shift toward nucleation (as women expect close emotional bonds with their spouse) and higher investment in

children. Mass education has paved the way for the expansion of mass media, where books, newspapers, movies, radio, and television all reinforce western cultural values of nuclear families and smaller family size.

Following the directional change of the intergenerational wealth flows, where parents provide more for children than is reciprocated, economic rationality dictates no fertility, but social and psychological forces keep fertility from falling to zero. Fertility decline, as Caldwell describes it, is essentially about changing attitudes and values about family structure, which influences the economics of the family and results in a changing directional flow of goods. We can observe societies where there are large urban populations, some proportion of children are attending school, many people are engaged in a market economy, but if the flows of wealth remain from children to adults, then high fertility remains.

In other regions of the world, traditional value systems dominated modernization for some time. As most regions of the world have begun to evidence reduced fertility, the theory was modified to focus on the cultural transmission of western values via mass schooling and cultural diffusion. Thus, in its most recent form, the theory examines fertility transition as involving three elements. 1.Cultural diffusion of individualist western values affects the economic costs of children, proceeding across regions of the world. 2.When such values permeate the cultural context, children no longer provide net flows of wealth to parents and cease to increase parental wealth. 3.The economic effects of value change, in turn, affect fertility desires, leading people to adopt practices that lower the number of children they have.

Empirical Applications of the Theory

Caldwell's theory of wealth flows has led to extensive empirical research. Wealth flows theory has been addressed empirically in two ways. 'Weak' correlational tests of the theory have been conducted to determine whether fertility levels respond to the economic contributions of children (De Tray, 1983; Dow and Werner, 1983). Those tests tend to support the theory in that fertility tends to decrease as children spend less time in productive activities.

'Stronger' tests have also been conducted in which wealth flows across generations are actually measured to determine whether, in fact, more wealth flows from children to parents when fertility is high. Those tests quantify production and consumption rates across age groups to determine net flows between generations over the course of the entire life span. Almost universally, the stronger tests do not support the theory.

The evidence shows that in high-fertility contexts children do not produce enough before they marry to overcome the huge investment they received from parents at young ages, and most elderly individuals still produce more than they consume (Cain, 1982; Kaplan, 1994; Lee and Kramer, 2002; Lee, 2000; Stecklov, 1999).

Kaplan (1994) measured the caloric yield by age and sex in three hunter-gatherer societies and found that children do not produce more than they consume until approximately 20 years of age, an age at which many individuals already had children of their own, and that elderly individuals are usually net producers. Many other studies have come to similar conclusions. Mueller (1976) studied 27 traditional agricultural communities and found that children did not produce as much as they consumed until late teens and never produce enough to cover their consumption. Lee and Kramer (2002) came to similar conclusions studying the Maya agriculturalists. Stecklov (1999) and Cain (1982), both analyzing economic returns to childbearing in developing countries, again found that child labor did not produce enough to compensate for consumption.

Finally, Lee (2000) compared intergenerational transfers across different economic and cultural systems, including hunter-gatherers, horticulturalists, agriculturalists, intensive agriculturalists, and one post-industrialized context. He found that the only context where there were upward wealth flows was the post-industrialized country, specifically, the contemporary United States, exactly opposite to the wealth flows prediction. This is due to the social security system, which allows older Americans the opportunity to retire and become net consumers. The data on consumption and production curves suggest that the only time wealth flows upwards is in low-fertility contexts with extensive social security programs, contrary to Caldwell's predictions.

Another critique of wealth flows theory is that Caldwell's description of family relations in pretransition societies may describe the African context well, but it describes other contexts, such as Asia, quite poorly, as Asian countries have reduced their fertility even though a strong extended family system remained intact (Mason, 1997). Several authors have argued that old-age care of parents is not an important determinant of fertility as some countries initiated pension schemes without a drop in fertility and others experienced large declines in fertility, even though children were still responsible for parents in old age (Cleland, 1993; Galor, 2012). Thadani (1978) argues that it is hard to test empirically the direction of causality between emotional nucleation and economic change and that it is possible that economic conditions lead to changing family structures instead of the reverse.

In spite of this growing body of evidence, a definitive conclusion will require more research. Existing studies, unfortunately, have not measured the benefits of increased political power and insurance that may accrue to large families, because they are difficult to measure. Caldwell has argued that those added effects could shift the results of empirical studies from the conclusion that children consume more than they produce to children actually becoming a net benefit to parents (Caldwell, 2005).

In addition, even though children may not provide net economic benefits when fertility is high, as was first predicted, many studies show that fertility is reduced when parents experience higher actual or perceived costs of children, which supports a weak version of Caldwell's theory (Clay and Vander Haar, 1993; De Tray, 1983; Dow and Werner, 1983; Nag et al., 1978).

Caldwell's theory was revolutionary in combining the role of cultural influences and economic optimization in fertility decision-making, which has led to much of the current fertility research among biodemographers. Today, researchers seek to understand how individuals make fertility decisions in

changing conditions (Kaplan et al., 2002; Kaplan and Lancaster, 2000; Shenk et al., 2013; Shenk, 2009) and understand how changing from extended kin networks of family organization to more isolated nuclear families influences fertility outcomes (Mace and Sear, 2005; Mathews and Sear, 2013a; Sear and Mace, 2008; Turke, 1989).

Evolutionary Approaches to Wealth Flows and Family Relations

Evolutionary anthropologists also focus on the links between fertility and intergenerational transfers. They share Caldwell's view that fertility will be negatively associated with wealth flows to children. However, their theoretical approach differs from traditional wealth flows theory on several fronts. The basic underlying assumption governing evolutionary approaches is that natural selection has acted on the physiological and psychological processes that govern both fertility and parental investment. The expectation is that natural selection favors genetic variants which tend to maximize the production of descendants in the long run. Overall, higher fertility results in greater number of descendants, but increased fertility trades off against offspring quality, which, in turn, affects their ability to survive and reproduce (see Fertility Theory: Embodied-Capital Theory of Life History Evolution).

This leads to a major difference in conceptualization of the factors determining fertility and parental investment. Evolutionary anthropologists expect that environmental and socioeconomic factors will determine the relationship between fertility and child outcomes, and therefore predict both parental investment and fertility (Kaplan, 1996). For example, the nature of child mortality risks alters how parents should allocate resources to offspring. Some risks may not be preventable by increased parental protection or provisioning, and others may be buffered by parental assistance. If increases in parental investment will be ineffective, as in the former case, maximization of fitness will be associated with higher fertility. In contrast, when increased parental investment greatly increases offspring survival, lower fertility is the expected outcome (Kaplan et al., 2002). Similarly, and perhaps more importantly, the relationship between parental investment and offspring income in adulthood is also likely to affect fertility decisions. Again, evolutionary anthropologists expect that the impact of parental investment on wealth of offspring will impact fertility decisions; the greater the impact the lower the fertility, holding all else constant.

Other socioeconomic factors may also determine the relationship between child outcomes and fertility. The impact of parental investment on offspring income, and hence the offspring's ability to produce and invest in children, is expected to affect parental investment, and hence fertility, indirectly. As parental help becomes increasingly effective in affecting child outcomes, the expectation is that fertility will decrease accordingly, holding all else constant. The role of culture in evolutionary models is informational. The relationship between the environment and offspring outcomes as a function of fertility, especially in the context of socioeconomic change, is not necessarily obvious to people. The behavior of other people can serve as a cue about those relationships. Thus, the causal relationships linking culture to fertility in evolutionary models is different from the view proposed by Caldwell. In the Caldwell model, culture change is a prime driver of behavior change, whereas in evolutionary models, culture change is driven by changes in the socioeconomic conditions people face, and hence is rather the effect of changing conditions rather than a causal determinant (Snopkowski and Kaplan, 2014).

There has been a long-standing appreciation that fertility behavior may be the result of economic factors and/or social network effects, it is only recently that evolutionary anthropologists have tried to explore how microenvironments influence fertility behavior. Within a local environment, individuals are exposed to different network influences, which lead to heterogeneity across communities. This allows for tests of the relative contribution of social network effects over and above those of individual characteristics. Recent work by Kaplan et al. (in press) compares individual-level and community-level effects on fertility outcomes among the Tsimane of Bolivia and find that individual-level effects explain most of the variance in fertility outcomes, while community-level predictors have little effect. In contrast, Colleran and Mace (2014), using a Polish sample, find that community-level predictors have significant effects on fertility outcomes, even after individual-level predictors are controlled for. These studies demonstrate that the role of cultural norms in predicting fertility outcomes is still not completely understood, but researchers are devising new and unique ways to test their effects.

There are still many areas of study for future research. With increasing globalization, local conditions lead to niches in the global economy, which, in turn, influence women's roles and have a direct effect on fertility outcomes. For example, in contexts with large garment industries that primarily employ women, such as Bangladesh, women face a steep tradeoff between work and child care. Women with children typically have to send children to their natal villages to be raised by kin. This is in sharp contrast to contexts where women's work has been integrated with child care and there is less conflict between women's work and child care. There are extensive possibilities to explore how socioecological factors affect fertility at a community level.

Role of the Family in Fertility Decision-Making

While Caldwell conceptualized the extended family as a family structure that required transfers from young to old members, other researchers have argued that extended kin operate to provide additional resources for childbearing (Hrdy, 2005). The loss of the extended family structure may mean that the costs of children become larger for parents because they cannot be dispersed to extended kin members (Turke, 1989) or that pronatal messages, which may come disproportionally from kin, are reduced as individuals are located further from extended kin members (Newson et al., 2005).

Evidence has been mounting for the positive effects extended kin (usually parents or in-laws) have on the survivorship of children and fertility rates. Children are more likely to survive in many contexts if grandparents are alive, with effects generally being strongest for maternal grandmothers (Beise

and Voland, 2002; Beise, 2005; Hadley, 2004; Kemkes-Grottenthalef, 2005; Lahdenperä et al., 2004; Sear et al., 2000; Sear, 2008; Tymicki, 2004). There is also evidence that grandmothers have positive effects on children's nutritional status (Gibson and Mace, 2005; Sear et al., 2000). In several contexts, grandmothers provide needed help to children and grandchildren; grandmothers reduce mother's work energy expenditure and reduce maternal direct child care among the Aka foragers of central Africa (Meehan et al., 2013), they reduce risk of grandchild mortality and low birth weight when they are the primary source of support for mothers in Puerto Rico (Scelza, 2011), and they relieve daughters of heavy domestic tasks in rural Ethiopia (Gibson and Mace, 2005). Finally, there is evidence that individuals who have close bonds with parents are more likely to engage in reproduction (Mathews and Sear, 2013a,b; Waynforth, 2012) and that having kin available who provide child care increase the likelihood of additional births (Bereczkei, 1998; Kaptijn et al., 2010). This thriving research area has demonstrated the positive effects grandparents have on grandchild outcomes, again providing evidence that resources flow from parents to children and grandchildren instead of the reverse.

Given that the variation in kin effects across contexts is not well understood and we expect kin to have differing effects depending on the local fertility norms and socioecologies, this provides a thriving area for future research. Further, we may expect variation depending on the type of kin member, as some kin are more closely related than others and some kin have their own reproductive opportunities, which may lead to kin reproductive conflict instead of cooperation. Empirical evidence shows mothers-in-law tend to have a positive effect on fertility outcomes for daughters-in-law (more so than mothers on daughter's fertility) (Sear and Coall, 2011), but we do not truly understand why this occurs. Both social and economic hypotheses have been brought forward as potential explanations, but future work will likely explore this evolutionary puzzle.

Conclusion

Research conducted in the past 30 years has provided support for the claim that parents adjust their fertility based on the actual and perceived costs of raising children, where higher costs and lower levels of productive work by children result in reduced fertility. Strong tests of the wealth flows theory provide evidence that the flow of wealth has not traditionally been from children to adults. In spite of this, Caldwell's theory of intergenerational wealth flows has spurred much research into the interrelationship of cultural values and economic decision-making, the amount of production and consumption across different age categories, and tests of differing hypotheses of the demographic transition. The interaction of economics and culture is still at the core of our understanding of fertility decline and understanding their interaction continues to generate new research. Finally, the evidence shows that grandparents provide tangible benefits to children and grandchildren, which promotes reproduction for children.

Abstract

Variation in fertility patterns in relation to environmental factors and mortality schedules can be understood using evolutionary life history theory (LHT). In addition to explaining differences within and between human populations, LHT allows us to make direct comparisons with other species. Here we discuss LHT, the concept of trade-offs, and the importance of this theory as applied to humans. We end by discussing the ways in which LHT potentially explains patterns of low fertility in contemporary industrialized society.

> Life histories lie at the heart of biology; no other field brings you closer to the underlying simplicities that unite and explain the diversity of living things and the complexities of their life cycles.
> Stearns, 1992: 9

In 2014, the world population topped 7 billion, with almost all observed population growth occurring in the less-developed world. At the same time, evidence suggests that global fertility rates are actually beginning to decline, with almost all developing nations showing some sign of entering a demographic transition (e.g., Sanderson, 2013). In the industrialized world, where fertility has been in decline for over a century, total fertility rates hit an all-time low in the 1990s, dipping below replacement levels. Yet, recent fertility projections suggest that this pattern may now be reversing, with fertility set to rise to replacement levels, and perhaps beyond, raising the intriguing possibility that reproductive strategies may be shifting in response to the conditions of the post-industrial world (Myrskylä et al., 2009, 2013). What determines the number of children a woman will have in her lifetime? How can we make sense of the fertility patterns we see, and understand why they vary in both time and space?

These questions have long engaged demographers, economists, and sociologists, but completely satisfactory answers continue to elude us. These are also questions that, in broad perspective, evolutionary biologists seek to answer about all species, as they relate directly to measurements of fitness (approximated by the number of descendants that contribute to future generations), and hence to the action of natural selection, the process by which adaptive evolutionary change occurs. Our goal here is to show how aspects of evolutionary thinking can be brought to bear on questions relating to human fertility patterns, and that, although we are not yet able to solve all the puzzles of human fertility variation, we can begin to address these issues in ways that productively augment more traditional social science approaches.

Life History Theory and the Cost of Reproduction

Life history theory (LHT) provides a robust evolutionary framework in which to situate studies of human reproductive and mortality schedules, in ways that also allow us to make direct comparisons with other species. An organism's life history is the combination of the probabilities of survival and fecundity that a species displays in its natural environment (Partridge and Harvey, 1988); it is therefore closely tied to the study of demography (Stearns, 1992). The theory of life history evolution posits that fitness is maximized by natural selection over the life span of an animal. This is not as easy as simply maximizing fertility at every age, as fertility in early life may be traded off for decreases in either fecundity, fertility, or survival in later life. That is, there is a cost to reproduction. (By fertility we mean the total number of offspring produced, whereas fecundity refers to the potential to reproduce.)

Why is reproduction costly? One reason is that there are ecological costs associated with the act of reproducing. For most (if not all) animals, the environment is a dangerous place: acquiring resources, mating, giving birth, and raising young are all activities that leave animals prone to physical injuries, exposed to disease, or at risk of death by predation (Roff, 1992). More importantly, reproduction is costly because it requires energy that must be diverted away from other bodily processes (the 'Principle of Allocation'). An animal's life history is a consequence of three biological processes that compete for resources in the body: repair (or maintenance), growth, and reproduction. Investment in reproduction inevitably decreases the amount of energy that can be invested in repair and growth and, as a consequence, decreases future fecundity and survival. These trade-offs – the costs paid in terms of fitness when a beneficial change in one trait is linked to a detrimental change in another (Stearns, 1992) – are a fundamental concept in LHT.

The cost of reproduction, and its associated trade-offs, not only affects an individual's own fecundity and future survival, but also that of its offspring. In an elegant study, Dijkstra et al. (1990) manipulated brood size (i.e., the number of chicks produced in a single breeding attempt) in kestrels, a small bird of prey, either adding or removing two nestlings to some nests (as well as leaving some nests untouched). They found that adding nestlings increased the total number of fledglings produced, but that the offspring in such nests had the slowest growth and highest nest mortality rates compared to nests that were reduced in size. Moreover, when raising an enlarged brood, male parents spent much more

 http://dx.doi.org/10.1016/B978-0-08-097086-8.34012-0

time in flight and flight-hunting, whereas female parents were lighter, and lost weight more rapidly. Most strikingly perhaps, the parents of enlarged broods also displayed lower survival. The cost of reproduction, therefore, is multifaceted, with both intragenerational effects (decreased survival of the parents) and intergenerational effects (reduced offspring survival, decreased mass of offspring).

Life histories are characterized by these kinds of trade-offs that, in one way or another, serve to balance the energetic resources allocated to current versus future survival and reproduction. The form such trade-offs take, and hence the life history trajectory followed, depends critically on the nature and quality of the environment an organism encounters because this will differentially influence the chances of survival and reproduction.

How Large and How Soon?

Many organisms must first reach a minimum size before they are able to reproduce, simply because a certain level of bodily development is needed to support any kind of reproductive function. Growth is often extended beyond this minimum body size, however, because a larger body size is beneficial for fecundity and juvenile survival. All else being equal, then, animals try to maximize body size. The amount of time an organism spends growing to achieve larger body size hinges directly on environmental conditions. Better quality environments lead to increased growth and hence larger, more fecund adult animals. In poor environments, growth is slowed due to reduced energy intake, which may lead to reduced adult size, but large body size may also be less favorable under such conditions, as this incurs greater costs of maintenance and repair. For a number of species, including humans, growth ceases entirely once reproduction begins (the so-called 'determinate' growth), and selection pressures and trade-offs change dramatically once this point is reached; hence the switch from the growth phase to the reproductive phase (i.e., the age of sexual maturity) is a particularly crucial transition in an animal's life history.

Sexual maturity is usually defined as age at first birth in LHT, rather than by any physiological measure of maturation (Stearns, 1992). The benefit of maturing at an early age is largely self-evident: it reduces the chances of dying before an individual has had the chance to reproduce. Furthermore, offspring of early-maturing animals will themselves mature earlier than those of later-maturing animals and hence start reproducing sooner. Delaying maturity when mortality risk is low can also be advantageous, however, because extended growth and larger size may increase the chances of survival, as well as initial and future fecundity, the number of reproductive events, and the quality of the offspring or parental care provided.

Environment-specific mortality risks thus strongly influence age at sexual maturity. Higher mortality reduces life expectancy, such that animals cannot 'afford' to postpone reproducing, and hence will mature at an early age, trading this off against a longer growth period and larger adult body size. Conversely, low mortality in later life results in later maturation, allowing individuals to reach a larger adult size. The relationship between low mortality and delayed age at first birth has consistently been documented, across species, across populations within species, and within populations. For instance, among humans, cross-national average age at first birth shows a strong negative association with mortality rates in those countries. Even at quite small scales, such as within a city, mortality predicts the timing of first birth (Nettle, 2011). Although Nettle (2011) did not consider the relationship between mortality and growth as the source of these differences, other studies have shown an interaction between patterns of growth, mortality, and age at maturity across populations (Walker et al., 2006).

How Varying Environments Lead to Reaction Norms

As the above makes clear, the trade-off between age and size at maturity, which in essence represents the trade-off between current and future reproduction, is environment specific. If a species occupies an environment that is either very stable over time or the species' range is very narrow, natural selection will likely have solved the optimality problem such that all animals will mature at a specific body size X and age Y (although, of course, there may be some genetic variation between individuals that gives rise to phenotypic or trait variation). Now imagine that a species occupies a broader range of environments and is likely to face more variable environmental conditions as a result. This variation produces variation in growth rates and age- and size-specific mortality rates (Stearns and Koella, 1986). Under poor environmental circumstances, for example, growth will be slowed substantially. If the animal still matured at body size X under such conditions, it would take considerable time to reach this point; this would be risky given that mortality may strike before the animal reaches this size. If, however, the animal matured at an earlier age, Y, it would do so at a very small adult size, which would also impose a cost in terms of future survival and fecundity. A different compromise between X and Y is therefore needed to reach an optimal outcome for this specific environment. When the environments that animals encounter are variable in this way, 'reaction norms' are likely to evolve. A reaction norm is a set of phenotypes produced by a single genotype across a range of environmental conditions, and allows animals to track the optimal trade-off. Thus, phenotypic variation across environments may represent the expression of an evolved reaction norm, which ensures an appropriate trade-off between life history components. It is also true that some of this variation can arise from genetic variation across individuals in the reaction norms themselves.

The finding that rates of mortality across neighborhoods within a city predict age at first birth potentially can be interpreted as an expressed reaction norm (Nettle, 2011), because these phenotypic differences are unlikely to be (solely) due to genetic differences. Cross-population differences in age at first birth and patterns of mortality also fit well with LHT predictions: as the chance of reaching adulthood decreases, earlier onset of sexual maturity is generally observed (Walker et al., 2006). These patterns cannot, however, be unambiguously interpreted in terms of a reaction norm. In some Pygmy groups, for instance, sexual maturity occurs early and at very short

adult stature in environments of high mortality, and these characteristics are linked to distinct hormonal profiles with a genetic basis, suggesting the action of natural selection on early reproduction, rather than a plastic response to the environment. Indeed, testing for reaction norms remains an ongoing challenge as we still know surprisingly little about population-level patterns and individual-level biological processes in relation to age, growth rates, and size at maturity (Walker et al., 2006; Stearns, 1992).

How Many and How Much to Invest?

The next decision an animal faces once it has reached the reproductive phase is how many offspring it should produce, and how much it should invest in them. Any energy invested in the current offspring entails costs in terms of future survival and offspring production (Dijkstra et al., 1990). Although in many species, clutch (or litter) size can be adjusted, the same does not hold for all animals, including humans. Humans are generally restricted to a litter size of one, as are most other primates. Current theorizing suggests that producing a low number of offspring on a regular basis is adaptive in primates, because of their long life span and their reliance on a highly variable resource base, both of which leave them vulnerable to unpredictable shortfalls in available resources – and hence to low juvenile survival – during any particular breeding attempt (Jones, 2011). By limiting their reproductive effort to a single offspring at a time, mothers are able to invest more in their own survival, thereby increasing their life span and ensuring a larger number of reproductive events. In this way, reproductive failure in any one year is not catastrophic in terms of fitness (Jones, 2011).

There is, however, a rather unusual case in humans, which sheds light on the cost of reproduction, namely twinning – a relatively rare event (0.6–4.5%; Lummaa, 2007). Compared to women who have singleton births, mothers of twins have a higher risk of dying during childbirth, longer subsequent birth intervals, are more likely to terminate reproduction entirely, are more likely to fail to raise their next offspring, and are more likely to die earlier in the postreproductive phase (Lummaa, 2007). Moreover, twins are usually smaller in size than singleton births and experience lower survivorship (Sear et al., 2001). Mothers who give birth to twins are also larger in size than those who give birth to singletons (Sear et al., 2001), suggesting that twinning is indeed costly and that larger maternal body size is needed to bear these increased costs. The cost of twinning extends to both the parents (intragenerational) and the offspring themselves (intergenerational). Twinning, however, may also provide advantages in terms of fitness, if the costs of reproduction are offset by the benefits of gaining two offspring from a single birth event (Sear et al., 2001). For example, Lummaa et al. (1998) observed that lifetime reproductive success of mothers of twins was higher in areas of high resource availability, but lower in areas of low resource availability compared to mothers of singletons. Moreover, they showed that rates of twinning were higher in those areas in which twins provided fitness advantages, providing some support to the notion that natural selection may maintain, or even favor, twinning under some circumstances (Lummaa et al., 1998).

Although humans generally produce only one offspring per reproductive event, they are rather unusual in that, due to a long period of offspring dependence, parents usually raise several offspring of varying ages simultaneously, with resources distributed over all children raised. Indeed, humans are different from other primates in a number of respects: in addition to a lengthy developmental period and dependence on caregivers, we also possess large expensive brains, have a relatively long adult life, and display intergenerational systems of resource flow. All these traits have been argued to stem from the fact that humans are adapted to a particularly skill-intensive foraging niche, in which many years of learning are needed to reach high levels of competence (Kaplan et al., 2002). Attempting to raise a series of children whose demands on parental care overlap in time inevitably leads to conflicts, given that resources are finite. As children are both heavily dependent and energetically costly in their first years of life, the biggest conflicts often arise when births are very closely spaced in time. Indeed, there is substantial evidence that shorter interbirth intervals increase child mortality (Hobcraft et al., 1983; Koenig et al., 1990). The negative effects of twinning on survival as discussed above – a case in which the lowest possible interbirth interval is achieved – also fit well with these patterns.

The adverse effects of short interbirth intervals are generally considered to be a consequence of either 'maternal depletion syndrome' (i.e., mothers do not have sufficient time to recover from the physiological and nutritional demands associated with pregnancy, parturition, and breast-feeding) or the competition between siblings over parental resources (Koenig et al., 1990). These effects are arguably strong enough to have led to the evolution of lactational amenorrhea: a postnatal period of infecundity that arises as a consequence of hormonal changes induced by breast-feeding (Howie and McNeilly, 1982). Indeed, breast-feeding is the most widely used method of controlling birth spacing in populations without modern contraception; the energetic demands of milk production are high, and nursing offspring represents a significant constraint on the availability of metabolic energy to support a new pregnancy (Ellison, 2003). As LHT predicts, then, investment in current offspring strongly limits females' ability to invest in future offspring.

Fertility, Longevity, and the Difficulties of Measuring Life History Trade-Offs

In principle, identifying trade-offs among different life history trade-offs should be straightforward, given an understanding of underlying theory and a species' ecology. In practice, however, it is not so easy. A consideration of the trade-off between fertility and survival illustrates this point perfectly. For species that reproduce repeatedly, like humans and other primates, this trade-off is dependent on both the spacing of births and on the total number of dependent young that need to be raised to adulthood. Increasing resources in reproduction detracts resources from both parental investment into children (which should reduce their quality

and hence their chances of survival) and also from bodily maintenance (which should lead to reduced parental survival). Studies of the trade-offs between fertility, child survival, and parental survival, however, reveal anything but consistent results (Lawson et al., 2012; Gagnon et al., 2009), with both positive as well as negative relationships observed.

Although there may, of course, be plausible theoretical reasons why fertility can potentially increase child or parental survival (for example, under some conditions, children may be successful at procuring resources for themselves and the family, changing the dynamic of the trade-offs in such ecologies: Lawson et al., 2012), the variability seen may also reflect the difficulty of accurately measuring trade-offs. Obviously, experimental methods (such as manipulating clutch size or breeding experiments; Roff, 1992) are not possible in humans, and we are left with assessing either phenotypic correlations between life history traits or genetic correlations between traits based on family data. These correlational methods necessarily set boundaries on the confidence we can place on the results obtained. For example, unidentified confounding variables may give rise to relationships that are counter to life history predictions (it should be noted, however, that this problem is most definitely not restricted to humans; Partridge and Harvey, 1988; Stearns, 1992). One such confound is the quality of the individual, or more specifically, the energy budget the individual has at its disposal. To put this in everyday terms, one might predict that most people would be able to afford either an iPad or an iPhone, given the expense of such items, and so would have either one or the other, but not both (i.e., there would be a trade-off). For individuals with a larger bank balance, however, such compromises are unnecessary; they can afford to buy both an iPad and an iPhone. The presence of such differences across individuals in the resources available can easily obscure the true nature of the trade-offs operating (Noordwijk and Jong, 1986). Another complicating factor is that our ability to identify trade-offs may be clouded by the presence of genotype by environment interactions, such that different genotypes respond differently to different environments (see Stearns (1992) for further discussion). These underlying difficulties may account for variation in, or lack of, observed trade-offs in a population.

Even when a predicted trade-off is observed, we often cannot infer causality because of the correlational methods used. For instance, increased reproductive effort (i.e., higher fertility) should come at a cost of parental effort (i.e., levels of parental investment), and indeed recent studies show that high fertility is often negatively related to child survival (Lawson et al., 2012). It is also possible, however, that the causality here is reversed: when mortality is high, women may increase their fertility in an effort to 'replace' deceased children, and/or they may preemptively increase fertility because they expect to experience a certain level of child mortality (Lawson et al., 2012; Winterhalder and Leslie, 2002). Although research on humans is unlikely to completely overcome the measurement difficulties identified above, the greater availability of databases containing LHT-relevant information, and their higher quality in terms of both sample size and level of detail, along with more advanced statistical methods, may well overcome these limitations to some degree (Lawson et al., 2012; Gagnon et al., 2009).

Quantity, Quality, and the Demographic Transition

Among industrialized societies, advances in medical science and public health have reduced child mortality to very low levels. Consequently, any reduction in parental investment may not manifest itself in terms of reduced offspring survival, but may be more nuanced. For example, high fertility is related to many adverse consequences for offspring due to competition between siblings. A larger number of siblings has been found to reduce grades at school, adult education and income, height, and health (Lawson and Mace, 2011), providing strong evidence for the trade-off between the quantity and quality of children.

It is exactly this trade-off that has been suggested, in the evolutionary literature, as the main explanation for the demographic transition (the switch from high to low fertility and mortality regimes that accompanies economic development and industrialization). Kaplan's (1996; Kaplan et al., 2002) embodied capital theory is worth highlighting in this regard as it explicitly incorporates aspects of prominent economic theories of quantity–quality trade-offs (Becker, 1960; Shenk et al., 2013), along with demographic theories of fertility (Bongaarts, 1978), into an evolutionary life history model. The theory treats growth, development, and maintenance as investments in stocks of embodied capital in both self and offspring. Importantly, this embodied capital includes knowledge and skills, as well as somatic tissue, thus bringing cognitive abilities into the realm of LHT. For humans, growth of knowledge may be as important as bodily growth with respect to adult competence and ultimately fitness maximization. There are a number of other theories of the demographic transition in the literature (see e.g., Shenk et al. (2013) for review), particularly those that focus more heavily on cultural explanations, but we will not discuss these here, as our aim is to illustrate how LHT attempts to explain this phenomenon in terms of the relevant trade-offs.

Kaplan's (1996; Kaplan et al., 2002) starting point is to argue that fertility regulation mechanisms are adapted to the selection pressures of the learning-dependent, skill-intensive hunter-gatherer foraging niche. Natural selection is hypothesized to have acted on human psychology such that people are sensitive to the environmental variation in learning opportunities and their likely payoffs, and levels of parental investment are calibrated accordingly. Individuals adaptively adjust levels of parental investment via breast-feeding (i.e., via one of the primary proximate determinants of fertility), lactational infecundability, as modeled by Bongaarts (1978), and nutritional flows to women (which also relates to lactational infecundability, both directly by affecting milk production, and indirectly via women's workloads and energy balance). Under conditions where all 'wealth' comes in the form of energy from food, the accumulation of embodied capital is automatically translated into offspring, via female reproductive physiology. Kaplan et al. (2002) demonstrate that, when applied to hunter-gatherer lifeways, a model of embodied capital maximizes fitness.

Kaplan (1996; Kaplan et al., 2002) then considers contemporary societies, asking what factors would prompt a decline in fertility. One key factor is argued to be the emergence of extrasomatic forms of wealth (livestock, land, money), which breaks the link between parental investment and reproductive physiology. Whereas somatic wealth translates directly into fertility under hunter-gatherer conditions, because our evolved psychological preferences for resources under such conditions amount solely to those energetic resources that can be stored in the body, this same psychology leads us astray when extrasomatic wealth can also be accumulated; this is argued to be because there is no mechanism in place to ensure that this evolutionary novel form of wealth is translated into fertility (Kaplan et al., 2002). Indeed, the model shows that a preference for wealth maximization under these conditions can lead to maladaptive behavior of the kind identified by Becker (1960), where people favor income and consumer goods over children. It should be noted, however, that this argument rests on the assumption that we possess an evolved psychological mechanism of this nature, and that this has failed to keep pace with the cultural and economic changes that characterize industrial societies. More stringent tests are needed to demonstrate the existence and operation of such a mechanism, and show that it is unable to respond adequately to wealth-accumulating environments.

A second factor linked to declining fertility that Kaplan (1996; Kaplan et al., 2002) identifies relates to the changing payoffs of embodied capital investments in low-mortality industrial contexts compared to hunter-gatherer lifeways. In essence, low mortality, combined with increased demands for skilled workers, is argued to result in high expected returns from investing heavily in the embodied capital of each child produced (in terms of educating them to the level required to be competitive in such societies). As family wealth is finite, this requires a trade-off between producing a few highly educated, skilled offspring versus a larger number of poorly educated, less-skilled, less-competitive offspring. Under such conditions, people calculate the number of children they believe they can afford to raise, given their wealth, and regulate their fertility accordingly.

Thus, even though in physiological terms, individuals have the capacity to produce large numbers of children, Kaplan (1996; Kaplan et al., 2002) argues that the high costs of providing them with the kinds of embodied capital needed to compete successfully, combined with the distorting effects of extrasomatic wealth on people's preferences, result in very few children actually being produced. Kaplan et al. (2002) therefore suggest that, although individuals trade off offspring quality against quantity exactly as predicted by LHT, in modern environments this number falls below that required to maximize fitness.

Yet, when extrasomatic energy use is considered (i.e., the use of fossil fuels, and the infrastructure required to support these) modern human fertility has decreased relative to other primate species exactly as expected given our increased energy consumption (Burnside et al., 2012). More specifically, human birthrates display an allometric relationship with energy expenditure in line with that of other species, and this pattern is quantitatively consistent with the life history patterns seen in other mammals, as well as nonindustrial human populations. As an example, the energy use of a woman in the United States nowadays is equivalent to the metabolic rate of a hypothetical 30 000 kg primate, and fertility rate is similar to what one would expect for a primate of this size (Burnside et al., 2012). Although industrial societies have larger more complex networks that can distribute larger amounts of energy resources than nonindustrial societies (pipelines, power grids, railway and road networks), such networks also require longer transport times for such energy to be distributed, and experience greater infrastructure costs. Burnside et al. (2012) therefore argue that, when all the relevant costs of raising children are factored into the equation, it becomes clear that offspring in industrial societies require exceptionally heavy investment, resulting in an extreme trade-off whereby very few children of very high quality are produced. When viewed from this perspective, the issue of whether people are behaving maladaptively and failing to maximize fitness remains open.

Indeed, there are a number of mathematical models demonstrating that small families may maximize fitness. Mace (1998) shows that when inherited resources contribute strongly to fitness and the cost of raising children is high, very low levels of fertility can be favored. Moreover, reducing fertility may enhance fitness in the far future if 'snowballing' effects of wealth are possible such that income generates income (Hill and Reeve, 2004), when long-term reproductive outcomes are more predictable (Winterhalder and Leslie, 2002) or when population dynamics are taken into account, such as (environmental) calamities resulting in demographic crashes (Boone and Kessler, 1999).

The most convincing empirical study to date, however, suggests that lowering fertility may not, in fact, maximize long-term fitness. Using data on over 14 000 Swedes born in the early 1900s, Goodman et al. (2012) showed that low fertility increased descendants' socioeconomic position (in line with the quantity–quality trade-off), but decreased their biological fitness. As the period covered by this study includes many demographic and societal changes that individuals had never encountered before, it remains possible that people's decision-making was in a state of flux, leading to maladaptive behavior in response to these changeable circumstances. Indeed, people's ability to track and respond to risk is not perfect (Winterhalder and Leslie, 2002). Although highly speculative, it seems possible that, as shifts in mortality schedules and costs of raising children may now have stabilized, people may be able to make more accurate assessments of environmental circumstances, and adjust their fertility in ways that ultimately contribute to higher fitness. Recent forecasts indicating that fertility may again be on the rise in some European nations (Myrskylä et al., 2013) can perhaps be interpreted in just this fashion.

Conclusion

The social sciences have been very successful in identifying the relevant determinants of fertility, both within and between populations (Balbo et al., 2013), but these determinants are often studied in a disjunct fashion. A life history approach posits that reproduction is inextricably linked to other processes

in the life cycle of an animal, with ecology determining how energy is allocated to these processes, and it thus argues that all aspects of the life cycle should be studied in tandem. The currency that is optimized in LHT, and more generally evolutionary theory, is the number of surviving offspring (or even the number of surviving offspring that contribute to the next generation). Incorporating such measures into studies of fertility, in addition to the number of children born per woman, would bring evolutionary and social science approaches closer together. A union of these approaches will augment and enhance our understanding of fertility, while placing humans in their appropriate evolutionary context, allowing us to make direct comparisons with other species.

Fertility Transition: China

Wang Feng, University of California, Irvine, CA, USA

Abstract

China's fertility transition followed a long historical tradition as Chinese families resorted to a variety of mechanisms to regulate the size and sex composition of their offspring long before the modern transition. The fertility transition was highly compressed in time, completed mostly in only a decade time. While China's transition was facilitated by a strong government birth control program, most of it was completed when China launched the extreme birth control policy known as the one-child. Such a compressed fertility transition, followed by more than three decades enforcement of the One-Child policy, has led to a series of long-term social and economic consequences.

Between 1970 and 1980, in one decade's time, China's national fertility level was cut in half. Following a decade of fluctuating around the level of two children per couple in the 1980s, fertility level in China dropped to below the replacement level and has stayed at that low level for over decades since the early 1990s. China's fertility transition, most notably in the 1970s, is the most drastic fertility decline observed among all human populations of significant size, aside from wars, epidemics, and famines. As the largest population in the world, China's fertility transition has also had the greatest impact on the slowing down of the world's population growth. This article reviews the process, historical background, the roles of the government programs and other factors, and the consequences of this transition.

Process of Fertility Transition

At the national level, China's fertility transition began in the early 1970s. In 1970, the total fertility rate was 5.8, close to the highest national level recorded for China. In the following decade, a most drastic reduction in fertility occurred. China's total fertility rate declined to 3.6 by 1975 and to 2.3 by 1980. The fertility level fluctuated between 2 and 3 throughout the 1980s. For the first time, it dropped to below the replacement level of 2.1 in the early 1990s and soon afterward, to a level of 1.5 and has stayed around such a level ever since. China, in other words, completed its fertility transition in two decades, from 1970 to 1990.

In China's urban areas and among the more educated subgroups of the population, the fertility transition began much earlier, dating back to the early 1950s (Lavely and Freedman, 1990). Since 1957, urban Chinese fertility declined almost consistently, with only one exception when fertility rebounded in 1963 after a plunge caused by the Great Leap Forward famine. By 1966, urban total fertility dropped to 3.1, and since 1974, it has never been higher than 2. In Shanghai, China's most cosmopolitan city, the total fertility rate dropped to below the replacement level (of 2.1 births per woman) for the first time in 1964, and to below 1 in 1975. By 1970, on the eve of China's first national family planning program, use of contraception and abortion among young women had already risen to 35 and 20%, respectively, in cities. Even in the countryside, over 15% of women at age 35 had already used a modern contraceptive method, and 7% had had at least one induced abortion.

In China's rural areas, where close to 80% of the population resided in the 1970s, fertility transition did not begin until much later, around 1970. In fact, during most years between 1950 and 1970, rural fertility showed signs of increase under the collective commune system. Fertility generally stayed at a level of above 6, with the exception of the Great Leap Famine years of 1959–61, when rural fertility was nearly halved. Consistent fertility decline in rural China began after 1970. The total fertility rate dropped to 5 by 1973, to 4 by 1975, and to 3 by 1979. During the 1980s, the total fertility rate fluctuated mostly between 2 and 3. In the early 1990s, it dropped to the below replacement level as was the case nationally.

There were also regional variations in the fertility transition in rural China. In provinces with a more advanced economy and a stronger tradition of population control, such as the lower Yangtze provinces of Jiangsu and Zhejiang, rural fertility declined earlier. In 1973, when the national level was 5, the total fertility rate was only 2.8 and 3.5 in these two provinces. By comparison, rural fertility was much above the national average in economically less developed provinces: it was 7.4 in Guizhou and 6.5 in Gansu (Coale and Chen, 1987).

Historical Background

China's large population size, along with a strong cultural preference for sons and a practice of early and universal marriage among Chinese women, have often led many to believe that the Chinese did not attempt to control fertility before China's contemporary fertility transition. Malthus, for instance, stated that "To account for this population, it will not be necessary to recur to the supposition of Montesquieu, that the climate of China is in any peculiar manner favourable to the production of children, and that the women are more prolific than in any other part of the world." Among the causes he identified is "The extraordinary encouragements that have been given to marriage, which have caused the immense produce of the country to be divided into very small shares, and have, consequently, rendered China more populous, in proportion to its means of subsistence, than perhaps any other country in the world" (1872/1971: p. 101, 103).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31077-7

Contrary to such earlier observations, many Chinese controlled their demographic outcomes in the past by relying on multiple mechanisms. The best-documented and most widely cited examples pertain to infanticide, especially female infanticide (Lee, 1981; Lee et al., 1994; Lee and Campbell, 1997). Chinese families killed some of their newborns in order to achieve their desired goals of the number and sex composition of the offspring. Poor harvests and economic difficulties also exacerbated the practice of infanticide.

Moreover, studies of Chinese historical population data also reveal that the Chinese fertility within marriages was significantly lower than their pretransition European counterparts (Barclay et al., 1976; Lee and Wang, 1999). Such a lower marital fertility level was achieved by a much longer interval between marriage and first birth, longer interbirth intervals, and earlier stopping. The same rationales that motivated infanticide also operated for fertility control behavior. Chinese parents sped up or slowed down reproduction according to the number and sex composition of existing children, and to their familial economic circumstances (Wang et al., 1995; Lee and Campbell, 1997; Zhao, 1997; Lavely, 2007). Fertility control in the past relied mainly on sexual abstinence, prolonged breast-feeding, and to a lesser extent, abortion and traditional contraceptives (Lee and Wang, 1999).

These behaviors suggest that controlling births is not a novel idea to the Chinese population. The contemporary fertility transition did not require new ideas of regulating population behavior, but rather a new environment in which fertility control became necessary and feasible. In contrast to traditional birth control, which relied on both prenatal and postnatal methods, the modern fertility transition is mostly prenatal, facilitated by new contraceptive and abortive technologies. Historical traditions of demographic control not only lay the foundation for contemporary fertility transition in mainland China, they also help explain the similarities in the pace and patterns of fertility transitions observed in several populations. In spite of having different political and economic systems, mainland China, Taiwan, Hong Kong, and Singapore all exhibited highly similar patterns of fertility transition, partly due to a shared cultural tradition (Coale and Freedman, 1993). The Chinese fertility transition process is therefore fundamentally a continuous process, extending a long tradition of demographic control.

Government Programs and Other Factors

The most prominent feature of China's fertility transition is the role played by government family planning programs. The most drastic fertility decline coincided with the launching of forceful government policies and programs of population control. Development of government policy can be traced to the early 1950s. Early concerns of rapid population growth and the need for a government family planning program emerged in the early 1950s, when China's 1953 census confirmed its large population size. Abortion was legalized and contraceptives began to be provided on a limited scale. Unlike later programs, which were motivated by government birth control goals, these early provisions were largely to meet an increasing demand among the population for birth control. These early efforts however were soon entangled in the ideological debates of whether China needed to control its population growth and they were interrupted by a series of political movements. As a result, it was not until the 1960s that the government seriously promoted birth control in urban and densely populated rural areas. Overall, government family planning programs at this early stage may have facilitated the early decline, but was not the main driving force.

Government intervention in reproduction reached a new phase in the early 1970s when the policy of *wan* (later marriage), *xi* (longer birth intervals), and *shao* (fewer births) was formed. Although largely accepted by most people on a voluntary basis, the implementation of the policy became increasingly intensified and regularized. The government utilized its control over the media to promote birth control as a national policy and mobilized a whole system of vertically controlled work and political organizations to implement the policy. Special government organizations in charge of birth control were also organized and expanded during this period. Official marriage age was stipulated to be 25 and 23 for urban males and females, and 22 and 20 for rural youths. Two children were considered the proper size for an urban couple and three for most rural couples. Under this program, Chinese ages at marriage rose sharply and fertility declined swiftly. Nationally, the female mean age at first marriage rose from 21 in 1970 to 23 in 1979, and the fertility level was halved (Banister, 1987).

In spite of this rapid fertility decline of the 1970s, the Chinese government was not content. Instead, motivated by a keen desire to increase quickly the per capita living standard within a short period of time, it launched an even more ambitious and a much more controversial birth control program in 1980. Known as the One-Child policy, it required each couple to have only one child, and was an emergency measure to further reduce China's population growth rate. Under the pressure of such an unprecedented and extreme policy, officials and especially birth control cadres resorted to all methods, including physical abuse in some locales, to meet the goals established by various levels of government. Women with two children, sometimes even only one, were required to have an intrauterine contraceptive device inserted, and women with three or more births were required to undergo sterilization. Pregnancies not meeting the requirement of birth control had to be aborted. Birth control campaigns were also launched in the 1980s, resulting in sharp increases in the numbers of abortions and sterilization (Hardee-Cleaveland and Banister, 1988).

This extreme policy met strong resistance from the Chinese population from the very beginning, especially from the vast population in the countryside. Whereas the earlier policies of birth control were by and large acceptable to Chinese farmers, this new extreme measure required them not only to forego their traditional perceptions of family and kinship, but also to reduce or even to remove their reliance on children for labor and old-age support. Popular resistance led to relaxation in the implementation in the Chinese countryside and to changes in the policy. As a result, Chinese couples in cities (accounting for about 20% of the population in the late 1970s) obeyed the One-Child policy, whereas most rural couples had two and some of them more than two children (Feeney and Yuan, 1994; Gu et al., 2007).

The draconian government policy may have masked the roles of many other factors underlying China's fertility transition process. In addition to the historical tradition of demographic regulation, many contemporary social and economic changes contributed to China's fertility transition. These changes include a drastic decline in mortality, especially infant mortality, the rise in nonagricultural and nonfamilial employment, rapid reduction in female illiteracy, and increased provision of social welfare, especially to the urban population (Peng, 1989). A changing social and economic context thus produced rapid adaptation to changes in childbearing in the Chinese mainland just as it did elsewhere in East Asia (Greenhalgh, 1988). At both the regional and the individual level, fertility differentials associated with employment type, residence, education, and income existed since as early as the mid-1950s (Lavely and Freedman, 1990). Factors other than government policy similarly have been shown to be crucial for China's below replacement fertility after the 1990s (Cai, 2010).

Consequences

With its speed and intensity, the Chinese fertility transition has also produced several distinctive consequences. The first is a unique social consequence, with a whole generation of single children and of parents with only one child. Among couples who would have completed their reproductive lives by the year 2010, 40% will have only one child. Among urban couples, for whom the One-Child policy was more effectively implemented, nearly 90% end up with only one child (Wang et al., 2012). Children grown up in these families have no siblings and in the future their children will not have any uncles, aunts, and cousins, all of whom are important parts of the traditional Chinese kinship network. Moreover, there will be a severe shortage in familial support at the old age. At least half of all parents of these single children will not be able to coreside with their married children in the future, when emotional and functional support from children is needed in old age.

Second, China's rapid fertility transition, with its resulting changes in population age structure, has had a profound impact on China's economy. Demographic dividend, the economic consequence of a favorable age structure, contributed at least 15% of China's historical economic boom in the closing days of the twentieth century (Wang and Mason, 2008). As that dividend diminishes, China faces the prospect of a rapid decline in the size of young labor force and an accelerated process of population aging. In less than 20 years and by 2030, China's ratio of working age population aged 20–59 to retirement age population aged 60 and over changes from 5:1 to 2:1. Even with China's record economic growth, its population has grown old before getting rich.

Lastly, China's rapid fertility transition has also led to an acutely unbalanced sex ratio between male and female births. Sex ratio at birth rose steadily, from 107 boys to 100 girls in 1981 to 115 boys to 100 girls in 1991, and to close to 120 boys to 100 girls in the first decade of the twenty-first century. The sex ratio among births of higher orders rose even more. Among second births, the recorded sex ratio rose from 107 in 1981 to 116 in 1985, and to 130 in 1993 (Gu and Roy, 1995). Much of this increased sex ratio is due to the widespread use of sex-selective abortion. Whereas the increase in the sex ratio may be attributable in part to its government program, the fact that similar increases in sex ratio are also observed in several other East Asian populations suggests this may at least be a temporary by-product of the fertility transition process in these societies. In China, such a lopsided sex ratio will have long lasting effect on marriage patterns and on population growth in the long run.

Abstract

'Culture' refers to shared systems of meaning or value, and their instantiation in material forms such as documents, artifacts, and institutions. Because 'culture' can refer to many things, explanations of fertility transition we call 'cultural' are a diverse set: some stress new contraceptive technologies, others social structures and institutions, others the movement of ideas or information between people, and still others the values and attitudes of individual social actors. This article provides a terse history of cultural approaches to fertility transition over the past seven decades.

'Fertility transition' refers to one element of demographic transition, the process by which mortality and fertility have fallen from approximate equilibrium at moderate or high levels to approximate equilibrium at low levels in most human populations over the past 200 years. As such, fertility transition is a special case of fertility change, characterized in its ideal-typical form as sustained decline in marital fertility following mortality decline with some lag, in association with increasing modernization, and with population equilibrium at the beginning and end of the process. Other kinds of fertility change, such as increasing proportion of births to unmarried women or changes in birth timing, have in recent years also been called 'fertility transitions,' although this usage remains contested. For the purposes of this article, the contestation is not important, as fertility transition narrowly understood and fertility change in a broader sense are amenable to the same kinds of cultural explanations.

'Culture' refers to shared systems of meaning or value, and their instantiation in material forms such as documents, artifacts, and institutions. Thus religion, gender, and even some kinds of politics are forms of culture, and the considerable majority of contemporary explanations of fertility are at least partially cultural ones. However, there is a second sense of the phrase 'cultural explanations of fertility transitions,' grounded in the intellectual history of population studies. Since approximately the 1970s, explanations of fertility decline have often been categorized into two opposing types – 'economic' and 'cultural' – where 'cultural' is defined almost entirely in opposition to its more coherent converse. Economic explanations posit that fertility outcomes are the product of individuals' utility maximization, usually about child numbers, so that fertility declines in response to the changing relative costs and benefits of children. What we have called cultural explanations, by contrast, are a diverse set. Under many other circumstances, these various explanations would not be classified as belonging to a single type: some stress technology, others social structures, others the movement of ideas or information between people, and still others cognitive states of individual social actors (see commentary in Mason, 1992: 1). However, they share a common opposition to the premise that fertility transition can be sufficiently explained by economics.

Cultural explanations of fertility transition include critiques of each aspect of the economic model. Some begin with the premise that the very idea of optimizing is a cultural construct that exists in certain times and places but not others. Others propose that individuals may indeed all be optimizing, but under such radically different circumstances as to make that claim irrelevant: if people's reproductive behavior is aimed at optimizing their relationships with ancestor-spirits, for example, then most economic models of fertility are going to be misspecified. Still others propose that reproductive behavior is so profoundly shaped by the flow of information, evaluation, and influence through social interaction that these flows must themselves be central to the analysis of fertility. Thus, some explanations we call cultural are in direct conflict with economic explanations – arguing against the premise of reproductive optimizing itself – while others are not necessarily inconsistent with the idea of means-ends rational decision-making about reproduction, but differ in emphasis. If people are seen as optimizing utility with culturally defined tastes under a complex set of cultural constraints, there can be an intellectual division of labor between those trying to understand the tastes and constraints on the one hand, and those trying to model the decision on the other.

Fertility transition sustains these competing explanatory models because the empirical corpus is complex and multiply construable. In favor of an economic perspective, nearly all data sets show a negative association between economic development and fertility. In favor of cultural explanations, that relation is highly variable across time and space in slope, strength, and the presence or absence of thresholds. Cultural explanations often draw attention to this diversity, to the ways that the relationship itself has changed over time, and to cases of asynchronous change: where fertility fell much sooner or much later than would have been predicted by economic drivers alone. Bongaarts and Watkins articulate the now common view: "variation in widely available standard measures of development … provides only a partial explanation of fertility differences between countries" (1996: 642), and the remainder of the explanation lies in social interaction – one of the processes commonly called 'cultural.'

Economics and Culture United in Institutions

Many early descriptions of fertility transition integrate economic and cultural perspectives. Although commonly cited

as attributing fertility decline to economic development alone, Notestein (1945) has a richly nuanced interpretation of fertility, which gives an important role to cultural change. He argues that fertility decline followed from the "growing individualism and rising levels of popular aspiration developed in urban industrial living" through which "the individual came to depend less and less on the status of his family for his place among his fellows" (1945: 40). Notestein saw the changes on fertility caused by economic development to occur largely *through* cultural transformations, both ideational (values and tastes) and institutional (constitution of the family and household, assignment to social roles).

The 1950s saw a substantial increase in studies into the relationships between culture, institutions, and demographic outcomes as anthropologists, sociologists, and demographers worked together to make sense of population processes in poor countries. Many of these authors made explicit links between the historical fertility transition in Europe and then-incipient fertility transitions in poor countries. Kingsley Davis and Judith Blake (1956) proposed a framework for thinking about the relationship between social structures – such as norms against intercourse during breastfeeding, or practices linking first marriage to inheritance – and fertility, through the now-famous intermediate fertility variables. While Bongaarts' reformulation of this idea in 1978 significantly downplayed the importance of social organization, the original Davis and Blake paper is a sociological argument about how roles, norms, and institutions influence fertility regardless of individual fertility intentions.

The functionalist approach to culture and fertility found in Davis and Blake was widespread in the 1950s. Among the prototypical works of this period is Frank Lorimer's 1954 book *Culture and Human Fertility*, published by the IUSSP in conjunction with UNESCO, including a tepid introduction by Frank Notestein, and contributions by anthropologists Meyer Fortes and Audrey Richards among others. The book is important less for its conclusions than for its approach, which is to treat fertility as an integral part of social systems, intimately linked to institutions of kinship and family, land tenure and inheritance, religion, education, and cultural attitudes. Most of the book focused on contemporary poor countries. However, in Chapter VI Lorimer focuses on the demographic transition in England and France, asking why the decline of fertility was so early in France and so late in England. He suggests that the cultural ideas introduced by the French revolution were critical to fertility change in that country, and concludes that "the record is clear on two negative points of theoretical importance: first, a trend toward increased control of fertility is not necessarily dependent on large-scale industrialization; secondly, the rapid introduction of mechanical industries into a previously non-industrial society does not automatically bring a trend toward increased control of fertility" (1954: 217). Whereas Notestein argued that economic changes would drive down fertility through changes in cultural practices, institutions, and ideas, a decade later Lorimer was arguing that economic changes were neither necessary nor sufficient for fertility declines, and suggesting that changing cultural ideas and cultural institutions could cause fertility to fall.

For Lorimer as for Davis and Blake, 'cultural' explanations of fertility depend very heavily on institutions – particularly those of kinship and family, but also broader social institutional arrangements, such as those concerning wage work, political participation, and the church. In this way, their arguments are largely consonant with claims of universal economic rationality, but where culture sets both the preferences and the constraints within which that rationality applies. This same view is seen several decades later in the influential work of John Caldwell.

Australian Caldwell had his first academic position at the University of Ghana (1962–64), and Ghanaian family life dramatically shaped his thinking about fertility. In the paper 'The Cultural Context of High Fertility in sub-Saharan Africa,' Pat and John Caldwell argue that African cultural systems are "seamless wholes … molded by stress on ancestry and descent" (1987: 410). For Caldwell, culture is the unity of institutions and ideas that together determine what individuals will try to achieve, and what constraints they will face. He argued therefore that "in societies of every type and stage of development, fertility behavior is rational, and fertility is high or low as a result of economic benefit" but that "[w]hether high or low fertility is economically rational is determined by social conditions" (1976: 355). These 'social conditions' include both institutions and values and attitudes, particularly concerning how children should be raised, and what obligations they have to their parents, which result in net wealth flows going either from parents to children (in low-fertility societies) or from children to parents (in high-fertility societies). Thus Caldwell's work continues the tradition set out by Notestein in which cultural and economic explanations of fertility transition are complementary and compatible, as people make choices that are rational within their own cultural context, and culture is largely defined by institutional forms.

Culture as (Potential) Interaction

A quite different view of culture emerged out of the European Fertility Project (EFP), started in 1963 by Ansley Coale at Princeton University. Coale sought to create a quantitative record of the European fertility transition, and to determine the temporal associations between social and economic circumstances and the timing of fertility decline across some 600 provinces in Europe. Collaborating with a large number of graduate students, Coale determined that the timing of fertility decline in relation to economic development varied considerably across the continent, but was geographically and linguistically clustered. Years later, Coale summarized the findings: "Adjacent provinces sharing the same language or ethnic origin were often alike in fertility even though different in educational levels, infant mortality, and the proportions living in cities. At the same time, adjacent provinces that had different cultural background … were not alike in fertility" (Coale, 1987: 21). That is, Coale and his students concluded that demographic change occurred through social interactions, facilitated by cultural similarity. The contribution of this remarkable work was not, as is often stated, to introduce demographers to the idea of culture. That had been done by Davis and Blake, Lorimer, and others in the 1950s. Rather, the key contribution of the EFP was to expand our understanding of culture in two ways. First, after the EFP, demographic understandings of fertility had to include the channels of information and influence along which changes in

ideas and values could flow. This lead in a relatively direct way to the contemporary foci on social networks and diffusion (*see* Fertility and Social Networks). Second, and more tentatively, several of Coale's students opened up ways of thinking about microlevel variation in ideas and values, whether through a focus on fertility decline forerunners (Livi-Bacci) or by pushing the implications of the empirical model to their theoretical conclusions (Watkins). This view of culture as plural and interactive is strikingly different from the bounded, stable, and institutional models of the functionalists of a decade before.

As Coale sought to make sense of the early findings of the EFP, he proposed a rethinking of demographic transition theory along cultural lines. In 1973, he presented three preconditions for a sustained decline in marital fertility. First, child numbers must enter into the 'calculus of conscious choice' – that is, parents must be able to entertain the idea that they could choose, even approximately, the number of children that they bear. If this precondition is not universally met, then it means that some parents or potential parents are not optimizing utility through their reproductive behavior, in striking contrast to the view of Davis or Caldwell. The second precondition states that lower child numbers must be perceived as advantageous by parents. Note here the key word 'perceived': while the objectively measured changing costs and benefits are surely related to parents' perceptions of the relative advantages of different family sizes, these two are not the same. Finally, Coale's third precondition states that parents must have access to an effective and acceptable means of fertility limitation. That is, some pregnancies arise because people either lack the information about how to prevent them or are unwilling to use available methods to prevent pregnancy. This is where technological innovation becomes part of a cultural explanation of fertility decline. In theory, any couple at any time in history could have used periodic or permanent abstinence or withdrawal to reduce fertility; Coale suggests that they either did not know how or were unwilling to accept such dramatic limitations on how and when they had sex.

Economists have argued that the burdens of a child so outweigh any potential burdens associated with fertility limitation that Coale's third precondition must always be met. But several demographers have shown that innovations in contraceptive technologies or knowledge do matter for fertility behavior, at least in some circumstances. For example, Shorter, Knodel, and van de Walle (1971) use data from the EFP to show that in a number of European countries, marital and nonmarital fertility declined in parallel. Since there were essentially no incentives favoring nonmarital fertility in Europe at this time, this suggests that: "the behavior of unmarried and married women was modified … as a result of obscure changes in the attitudes toward reproduction, and in the knowledge and acceptability of contraception and abortion" (Shorter et al., 1971: 393).

The EFP continued from 1963 until 1986. It produced to at least 10 books, dozens of articles, and nearly an entire generation of eminent demographers. Of the students of the EFP, none has been more influential on the topic of culture and fertility than Susan Cotts Watkins. Her 1991 monograph *Provinces into Nations* shows that from the middle of the nineteenth century to the middle of the twentieth, European fertility not only fell, but also became far less variable, particularly within national boundaries. She posits that fertility behavior is always influenced by social norms about how many children to have and when to have them, norms shared through social communication. However, Watkins argues, the mechanisms through which this social communication occurs have changed: in 1870, local gossip was the primary mechanism, whereas by 1960, newspapers and other national media dominated; as a result, the homogenizing effects of social communication on fertility are larger, and often correspond with the borders of nations. For Watkins, culture is thus centrally about interaction, both as a source of new ideas or information, and also as an "evaluative cloud of conversation" (Hammel, 1990: 467) which influences individual action. As a result, we cannot think about culture only through institutions, nor can we think about it as an individual trait. Culture is therefore something that *occurs* rather than something that endures, and it occurs particularly in communication.

In the mid-1990s, Watkins began work on contraceptive and fertility change in Africa, first in Kenya, then later in Malawi. This work continued many of the same themes developed in her European research, particularly concerning the importance for fertility of local systems of meaning and the role of social communication in their continuation and change, but with the advantage that she could collect data 'in real time' as new ideas diffused and changed (see Watkins, 2000). In order to show how social communication works, Watkins set out to collect rich data on networks over time: who talks to whom, about what, and to what effect? With Ann Swidler, she has also explored collecting data about natural conversations overheard in public (Watkins and Swidler, 2009). The projects in Kenya and Malawi have been important not only for the quality and quantity of data and publications, but also – like the EFP – as a training ground for a whole generation of talented and culturally oriented demographers, including Alex Weinreb, Nancy Luke, Jenny Trinitapoli, and many others.

Culture as Schemas, Attitudes, Values, and Beliefs

Whereas Watkins and others have focused on culture as interaction, seeing as central the conversations and social relationships through which ideas and influence flow, others have focused more on the *content* of culture, particularly as it is held in the mind: schemas, attitudes, values, and beliefs. An explicit study of the relation between fertility and these kinds of mental states first came to prominence in an attempt to understand reproductive differences and short-term change among married couples in the United States in the work of Princeton professors Norman Ryder and Charles Westoff on the National Fertility Studies (NFS) beginning in 1965, about the same time as Coale's EFP. The NFS framed reproduction as a decision made by a woman and her husband on the basis of a range of attitudes, values, and beliefs. Thousands of married American women were interviewed about their ideas and beliefs, some related closely to contraceptive practice (e.g., Should the federal government support birth control programs? Do you approve or disapprove of sterilization operations for men?), and others more broadly cultural, and particularly cultural-religious (e.g., What is your religion? How religious-minded are you?).

The NFS led to a considerable body of work on the values, attitudes, and beliefs related to fertility, both directly

(e.g., Ryder and Westoff, 1971; Westoff and Potvin, 1967), and indirectly (e.g., Frejka and Westoff, 2008; Simons, 1995). The early work in this genre is well-represented by Clifford, who argues that socioeconomic forces "exert their influence [on fertility] through the determination and reinforcement of certain value orientations which, in turn, have varying degrees of compatibility with particular fertility patterns" (1971: 38). In some later work, the causal link that Clifford asserts between socioeconomic conditions and values is attenuated, or even absent. Lesthaeghe, for example, argues that changes in values and ideas were largely responsible for the European fertility decline, and that these changes were largely autonomous of socioeconomic change (1983: 412), arising instead from the spread of secular individualism from the sphere of politics to the family. Fertility fell because people came to pursue "personal goals devoid of reference to a cohesive and overarching religious or philosophical construct" (1983: 415) after the social regulation of fertility gave "way to the principle of individual freedom of choice" (1983: 411). Lesthaeghe's more recent work on what he calls the "Second Demographic Transition" also proposes a central role for values in explaining fertility change (Lesthaeghe and Neidert, 2006). Similarly, Thorton's 'Developmental Idealism' stresses how fertility has changed in response to the spread and acceptance of Western values (2001). While Developmental Idealism has diffusion as its presumed mechanism, the model stresses the content of ideas – who values what – rather than the process through which those values move.

A highlight in the development of the study of fertility values is the edited volume *Dynamics of Values in Fertility Change* (Leete, 1999). The papers vary considerably in the degree to which they portray values as derived from socioeconomic circumstance, and also in the degree of causal power that they attribute to values. However, there is substantial agreement around three points noted in Casterline's terse conclusion. First "specific values are normally linked to other specific values and symbolic constructs, forming value systems and larger cultural systems" (Casterline, 1999: 358). It is therefore difficult to trace direct lines from individual values to particular reproductive behaviors. Second "all fertility behavior is value-driven, but fertility *change* is not necessarily driven by value *change*" (Casterline, 1999: 362, italics in the original), because, for example, fertility change may emerge as people continue to try to practice old values under new circumstances. Finally, "the values that have often been most decisive in determining fertility transition … have not explicitly referred to fertility, and, indeed, have sometimes been rather remotely related to fertility" (Casterline, 1999: 365). This is not only because values are often linked together, but also because family size is rarely a central value that organizes people's lives, whereas managing uncertainty, family solidarity, or belief in the church do so to a much greater degree. Taken together, these points suggest that understanding fertility behavior requires thinking about values as parts of cultural structures, rather than in isolation or only at the individual level.

Anthropology and Demography

Given that the discipline of anthropology created the contemporary concept of culture, it is noteworthy that anthropologists have featured so little in this article thus far. The reason is empirical. In the 1950s, Lorimer was in close conversation with structural-functional anthropologists in mapping out the social institutions, particularly of family and kinship, in which fertility is situated. But from the mid-1960s until the mid-1980s, even as many demographers were becoming increasingly interested in culture, anthropologists were largely absent from conversations about fertility and fertility transition. The conversation between demographers of fertility and sociocultural anthropologists was revitalized in the 1980s and blossomed in the 1990s with five major edited collections, at least a half-dozen major books, and several dozen consequential articles (the edited volumes are Basu and Aaby, 1998; Bledsoe and Pison, 1994; Greenhalgh, 1995; Kertzer and Fricke, 1997; Lesthaeghe, 1989; an especially important article is Hammel, 1990). The vitality of this period was intellectual, but also promoted by institutional resources: the Mellon Foundation provided substantial funding for training in anthropological demography starting in 1994, and the International Union for the Scientific Study of Population established a Committee on Anthropological Demography in 1998.

What distinguishes anthropological research on fertility in the 1990s is its characterization of reproduction as an activity grounded simultaneously in systems of meaning and systems of power. The word 'activity' here stresses that sex, contraception, abortion, and birth are things that people *do*, that they can do in new ways, that take time, and that are related to other, ongoing activities through which people constitute their lives differently in different times and places. To write about reproduction as a meaningful activity requires understanding how people think about births, but also how they think about a great many other things, such as gender, marriage, aging, work, religion, class, and progress. To write about reproduction as activity embedded in systems of power – whether primarily class (Kertzer, 1993; Schneider and Schneider, 1996), the state (Greenhalgh, 1994), or gender, marriage, and kinship (Bledsoe 1990, 1993) – entails understanding what about reproduction matters, to whom, and how access to reproduction is stratified.

This perspective is perhaps best accomplished in Bledsoe's 2002 monograph *Contingent Lives: Fertility, Time, and Aging in West Africa*. Here Bledsoe argues that high fertility in rural Gambia is an achievement for which women struggle and strategize, timing pregnancies in relation to their own bodily resources and social – particularly marital – circumstances in order to bear the full complement of children with which God endowed them. For Bledsie, 'pretransition' fertility is therefore not outside the 'calculus of conscious choice,' but its calculus is different than that assumed in most demographic texts, and therefore is hard to recognize. In the work of demographic anthropologists, culture became construed as a contested set of symbolic resources, constantly being reconfigured to suit new situations as people struggle to bear children when and how they want.

Recent Developments

Over the past 10–15 years, the concept of culture has become more central in the demographic literature on fertility than

perhaps ever before. Building on nearly seven decades of research, many in the present generation of fertility scholars agree that cultural forces and factors shape the kinds of reproductive contexts people face and the kinds of fertility behaviors that feel natural to them (see, e.g., Bernardi, 2003; Bernardi and Hutter, 2007; Fisher, 2006; Hayford and Trinitapoli, 2011; Hayford and Morgan, 2008; Johnson-Hanks, 2002, 2006; Obermeyer, 2000. Smith, 2001, 2004; Yeatman and Trinitapoli, 2008). The 'culture verses economics' framework that long organized debates about how fertility falls is often absent from this work. Also absent, often remarkably so, is the term 'culture' itself, particularly from titles, but often also as an explicit theoretical category. Trinitapoli and Weinreb's (2012) *Religion and AIDS in Africa*, for example, is a profoundly cultural book, which compellingly argues that to understand demographic outcomes we need to take religious practices and communities seriously, rather than assuming behavior on the basis of stated ideology, or studying only either individual-level behaviors or national differences. Examining how systems of meaning, practices, and resources are organized between individual, across communities and nations, Trinitapoli and Weinreb have culture in the center of their analysis, but tacitly: the term hardly appears. Similarly, Victor Agadjanian (e.g., 2001a,b) regularly writes about gender, religion, and ethnicity – all shared systems of meaning instantiated in material forms – but rarely uses the word 'culture.' Paradoxically, there is now so *much* culture in studies of fertility that the word has become almost obsolete.

Instead of arguing of the importance of culture as opposed to economic conditions, many contemporary scholars of fertility seek to understand the relationships among different parts of culture, and between these components of culture and reproduction. Whereas in 1970, demographers often said 'culture' to mean, 'something not explained by economic development,' today, the term 'culture' has a positive meaning, but its meaning is vast. It refers to shared systems of meaning or value, and the material forms that those meanings take, including institutions, performances, and artifacts. That is, culture structures social life, including reproductive practice. It is now clear that social networks, schemas and values, politics and social positions, institutions, religiosity, and the flow of ideas through media all matter for fertility. All of these things are part of culture. But they are also a disparate set, that work at different levels, in different ways, sometimes jointly and sometimes in opposition.

Moving forward, cultural explanations of fertility transition have to address the interplay of these multiple aspects. One attempt to do this is Johnson-Hanks et al. (2011), which proposes that we think about reproductive behavior as structured jointly by materials (objects, artifacts, institutions, and other kinds of resources) and by schemas (ideas that organize perception and action). Individual reproductive behavior in turn reinforces or alters the material and schematic structures in which it is embedded. This offers one way to integrate the material and schematic aspects of cultural systems without treating culture as a monolithic and inflexible whole. Simultaneous with new theoretical approaches, recent years have seen substantial innovations in the methods and data needed to study the relationships between structures of culture and fertility practices. For example, Margaret Frye (2013) has used card sort and optimal matching; Watkins and Swidler (2009) have used indigenous ethnographers; Bachrach (2013) has argued that the networked character of schemas means implies that new innovations in computational social science, dynamic systems modeling, 'big data,' and machine learning offer new opportunities for studying culture in relation to fertility. Since fertility itself is so deeply embedded in culture, explanations of fertility transition must also be cultural, and more than ever, we have a robust tool kit to take on that challenge.

Fertility Transition: East Asia

Noriko O Tsuya, Department of Economics, Keio University, Tokyo, Japan

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Japan, Korea, and Taiwan experienced rapid transitions from high to the replacement level of fertility in the earlier postwar decades, followed by further declines to well below-replacement levels of childbearing in the recent decades. While the earlier fertility transitions were due mainly to reduction of marital fertility through contraception and induced abortion, the more recent transitions to very low levels were due largely to decreasing marriage among young women. The declining marriage and fertility were associated with increases in educational attainment and paid employment among women at peak reproductive ages in the context of rapid economic transformations.

East Asia experienced extremely rapid declines in fertility after World War II. In the last decades of the twentieth century, fertility declined further to below-replacement levels in some countries of the region, notably in Japan, the Republic of Korea (called 'Korea' hereafter for linguistic simplicity), and the Republic of China (called 'Taiwan' hereafter for the same reason). These three East Asian countries share the Confucian cultural heritage, which places heavy emphasis on obligations to family and society, leaving little room for self-interest (Bumpass et al., 2009). Because the ultimate goal of their traditional family systems was the biological or social continuation of the family line, the most important obligation, especially for women, was to marry and have children (Greenhalgh, 1988; Tsuya and Bumpass, 2004).

Focusing on these three countries with similar familial cultural backgrounds, this article looks at the patterns and factors associated with their postwar fertility transitions. After an overview of trends in fertility levels, the article discusses changes in the two major demographic factors that directly influence fertility: the age pattern of women's marriage and fertility within marriage. The article then discusses major socioeconomic factors that affect fertility, including women's education and employment in the context of rapid economic growth, urbanization, and industrial transformation. The article ends with a summary of findings and discussion of their demographic implications, focusing on population aging and population decline.

Fertility Trends

Although there were differences in timing and magnitude, Japan, Korea, and Taiwan all experienced dramatic downturns in fertility after World War II (see **Figure 1**). In Japan, the total fertility rate (TFR) declined from 4.5 children per woman in 1947 to 2.0 in 1957. After this rapid decline, fertility stabilized at the replacement level (a TFR of 2.0–2.1 children per woman) for nearly two decades until it started to decline again in the mid-1970s. Since then Japan's fertility has been steadily declining to below-replacement levels, reaching 1.5 children per woman in the 1990s, and then 1.3–1.4 children per woman in the 2000s.

Figure 1 Total fertility rates in Japan, Korea, and Taiwan after World War II.

High fertility had persisted in Korea until rapid economic development began in the early 1960s. Then the TFR dropped precipitously from 5.9 children per woman in 1963 to 1.6 in 1986. This remarkable decline was followed by a modest upturn in the early 1990s until it started to slip again in the mid-1990s to very low levels (a TFR of 1.1–1.2 children per woman) in the 2000s. Taiwan's fertility transition was even more dramatic. Starting in the early 1950s, the TFR declined steadily and dramatically from 7.0 children per woman in 1951 to 1.7 in 1986. After a short pause, fertility began to decline again at the end of the 1990s, reaching a low of 1.0–1.1 children per woman in the late 2000s.

In summary, Japan experienced two fertility transitions, the first a rapid decline from historically high to replacement levels of childbearing shortly after World War II, and the second an ongoing decline since the mid-1970s from the replacement to very low levels of fertility. Korea and Taiwan both experienced phenomenal and almost continuous fertility transitions from very high to below-replacement levels from the early postwar decades until the mid-1980s, followed by further declines to extremely low levels of childbearing since the late 1990s. While many Western countries and some countries in other parts of Asia have also experienced or have been experiencing fertility declines to below-replacement levels, the fertility decline in East Asia is notable in its rapid pace and sheer magnitude. Today the levels of fertility in these three East Asian countries are all at or below what Kohler et al. (2002) considered as the 'lowest-low' fertility (a TFR of 1.3 children per woman).

Demographic Factors in Fertility Decline

In all three of these East Asian countries, the fertility transition is related directly to two demographic factors, namely, decreasing marriage among women and declining fertility within marriage. Because out-of-wedlock childbearing is minimal in East Asia, these two factors determine the overall levels of fertility. Demographic analysis indicates that roughly 90% of the decline in Japan's TFR between 1950 and 1975 was related to a reduction in marital fertility, and the remaining 10% was related to postponement of marriage among women. Similarly, around 70% of the TFR decline in Korea from 1960 to 1985 was due to declining fertility within marriage, and the remaining 30% was due to delayed marriage among women. In Taiwan around 75% of the decline in fertility between 1960 and 1985 was related to a decline in marital fertility, and the remaining 25% to later marriage. By contrast, the fertility decline in Japan after 1975 was due almost entirely to decreases in women's marriages. In a corresponding manner, the fertility declines from 1985 to 2010 in both Korea and Taiwan can also be attributed largely to later and less marriage among women.

In summary, the rapid transitions from high to the replacement level of fertility in Japan, Korea, and Taiwan after World War II were mainly the product of declining fertility among married women. On the other hand, unlike many countries in the West in which unmarried childbearing is common (van de Kaa, 1987), the more recent transitions to below-replacement fertility in these East Asian countries were, in the context of little childbearing outside marriage, due largely to declines in marriage among young women.

Reduction in Marital Fertility

The dramatic fertility declines from high to replacement or subreplacement levels in Japan, Korea, and Taiwan were caused primarily by reductions in fertility among married women, who gained control of their family size through contraception and induced abortion. The proportion practicing contraception among married women under the age of 50 years increased steadily in Japan from around 20% in 1950 to 61% in 1975 (Population Problems Research Council, 2000). After 1975, the prevalence of contraception stabilized at roughly 60%. With the expansion of government family planning programs, contraceptive practice spread rapidly in Korea and Taiwan from the 1960s to the early 1980s (Choe and Park, 2006; Chang et al., 1987). Contraceptive use among Korean wives aged between 15 and 44 years increased dramatically from only 9% in 1964 to 70% in 1985 (United Nations, 2000). In Taiwan contraceptive use among married women aged between 15 and 44 years also spread very rapidly from mere 4% in 1965 to 54% in 1985 (Sun, 2001).

Induced abortion is a traditional means of fertility control long practiced in East Asia. Along with the rapid increase in contraceptive use, rates of induced abortion also increased in the three East Asian countries. In Japan, the proportion of married women under age of 50 years reporting having experienced an induced abortion increased from 15% in 1952 to 41% in 1961 (Muramatsu, 1990). From the early 1960s to the 1980s, this proportion remained in the range of 30–40%. In Korea, the proportion of married women of reproductive age reporting having experienced an induced abortion increased from around 10% in the mid-1960s to nearly 40% in the late 1970s (Cho et al., 1982). Although the rate declined somewhat in the 1980s, induced abortion remains in the country as a viable option for terminating unwanted pregnancies. Although induced abortion had been illegal in Taiwan until 1985 (Wang, 1995), the reported use of abortion among married women of reproductive age rose steadily from the 1960s to the 1980s. The proportion of married women aged 35–39 years who ever had an induced abortion increased from 13% in 1965 to 42% in 1985 (Freedman et al., 1994).

Decreasing Marriage

As noted above, declining marriage has played a major role in the transitions of fertility to below-replacement levels in the three East Asian countries under consideration. Declining marriage for women in these countries is remarkable in light of the East Asian tradition of universal marriage and the cultural expectation that women should marry by their mid-twenties (Brinton, 1992). In Japan, the proportion never married was relatively stable among women in their twenties and thirties until the mid-1970s, when it started to increase precipitously. Between 1975 and 2010, the proportion never married rose dramatically from 21 to 60% among women aged 25–29 years, and from 8 to 35% among women aged 30–34 years (National Institute of Population and Social Security Research, 2013). Since the 1990s, there is also a sign of increasing nonmarriage: the proportion never married among Japanese women at age of 50 years – that is a commonly used indicator of the prevalence of permanent nonmarriage in

a population – edged up slowly from around 3% in 1975 to 5% in 1995, followed by a notable jump to 11% in 2010.

Korean women, too, are marrying increasingly later and less. The proportion never married among women aged 25–29 years rose slowly but steadily from mere 3% in 1955 to 18% in 1985. From 1985 to 2010, the proportion single jumped from 18% to 59% among women aged 25–29 years, and from 4% to 19% among women aged 30–34 years (Statistics Korea, 2011; Tsuya, 1991). Unlike Japan, however, there is not yet a clear sign of departure from the traditional pattern of universal marriage in Korea. The proportion never married among women at age of 50 years is still under 3% in 2010. Hence, while marriage has been increasingly delayed, universal marriage still remains intact in the country, although we cannot deny a possible 'spill over' of the increasing delay of marriage among younger age groups to older age groups, leading to increases in permanent nonmarriage among women in the coming years.

Taiwan has experienced, if not more, an equally dramatic decline in women's first marriage since the mid-1980s. The proportion never married slowly edged upward during the 1950s to the early 1980s: from 5% in 1956 to 23% in 1985 among women aged 25–29 years, and from only 2% to 9% among women aged 30–34 years. Between 1985 and 2010, increases in the proportion never married among women at the peak reproductive ages then accelerated: from 23 to 70% among women aged 25–29 years, and from 9 to 37% among women aged 30–34 years (Ministry of the Interior, 2011; Tsuya, 1991). Furthermore, similar to Japan, we can see a sign of increasing nonmarriage in Taiwan in recent years. While the proportion never married among women aged 45–49 years had been less than 3% until the mid-1980s, it increased notably from about 4% in 1985 to 10% in 2010.

Socioeconomic Factors in Fertility Decline

Although the time frame is different, Japan, Korea, and Taiwan all went through dramatic economic transformations after World War II, as characterized by the several decades of extraordinary economic growth and very rapid paces of urbanization and industrialization. This 'East Asian economic miracle' (McNicoll, 2006) preceded and progressed hand in hand with their fertility transitions, making them forerunners of the 'fertility revolution in Asia' (Leete and Alam, 1993). Concomitant with and as a result of the rapid economic development, educational levels and paid employment have increased dramatically in East Asia, and such gains have been especially remarkable for young women. These improvements in women's economic opportunities are among the major socioeconomic factors in fertility declines in the three East Asian countries under study (Chang and Li, 2011; Tsuya and Mason, 1995; Choe and Retherford, 2009).

Macro Economic Changes

Although the timing is different, Japan, Korea, and Taiwan all experienced extremely rapid economic growth after World War II. Starting in the mid-1950s, Japan's GDP per capita in constant prices grew at a phenomenal pace, quadrupling every 10–15 years until the late 1980s (Nakamura, 1981; World Bank, 1991). Between the mid-1960s and the mid-1990s, Korea's per capita GDP in constant prices also quadrupled every 10–15 years (World Bank, 1997). After doubling every 10 years from the mid-1960s to the mid-1980s, Taiwan's real per capita DDP quadrupled from the mid-1980s to the mid-1990s (Council for Economic Planning and Development, 2011).

In the course of rapid economic growth, these three countries experienced rapid urbanization. In Japan, the proportion of the population living in urban areas jumped from 37% in 1950 to 63% in 1960, and further to 91% in 2010 (National Institute of Population and Social Security Research, 2013). Korea has experienced similarly rapid urbanization, with the urban population rising from 21% of the population in 1950 to 83% in 2010 (United Nations, 2012). In Taiwan the proportion of the population living in cities of 150 000 or more inhabitants increased from 28% in 1965 to 72% in 2011 (Ministry of the Interior, 1976; Directorate-General of Budget, Accounting and Statistics, 2012a).

Along with rapid economic growth and urbanization, the three East Asian countries experienced dramatic changes in the structure of their industries. In Japan, the proportion of the workers employed in primary industries fell from 49% in 1950 to mere 4% in 2010 (National Institute of Population and Social Security Research, 2013). In Korea, the proportion of workers engaged in primary industries plummeted from 66% in 1960 to 8% in 2010. In Taiwan, the proportion of workers employed in primary industries dropped from 56% in 1952 to 5% in 2010 (Council for Economic Planning and Development, 2011).

Women's Educational Attainment

The dramatic economic transformations after World War II brought about important changes in women's status in the three East Asian countries under study. Educational attainment and paid employment increased, and these changes have affected fertility. Women's education is a key factor affecting fertility directly through the timing of marriage and marital fertility, and indirectly through employment and earnings (Cochrane, 1979). In Japan, a large majority of women were already receiving primary education before World War II; the most notable postwar change has been the steady, rapid increase in the proportion of women with higher education. The proportion of female high-school graduates advancing to higher education increased dramatically from 5% in 1955 to 56% in 2010, surpassing the rate of men during the 1990s (National Institute of Population and Social Security Research, 2013). The proportion of women aged 25–29 years who had higher education also increased from 4% in 1960 to 53% in 2010.

Unlike Japan, the educational attainment of Korean women was very low in the early postwar years and a sizable proportion of older women had no formal education. This situation has since changed dramatically, and the pace of increasing educational attainment was even more rapid than their Japanese counterparts. Only 3% of women born in 1937–41 had higher education, compared with 65% of women born in 1976–80 (Korea National Statistical Office, 2009). Taiwan has made

similarly impressive improvements in women's education. Like their Korean counterparts, educational attainment among Taiwanese women was very low in the early postwar years, with a sizable proportion of older women illiterate. But the female educational status has improved remarkably. While only 1% of women born in 1950–59 had higher education, the proportion with higher education increased to 28% among women born in 1970–79 (Chang and Li, 2011).

Women's Employment

With economies shifting rapidly from primary to secondary and tertiary industries, female employment underwent notable changes in the three East Asian countries under study. In Japan, although the overall female labor force participation rate has remained roughly 50% over the past 40 years, the proportion of working women in paid employment increased from 41% in 1960 to 84% in 2010 (National Institute of Population and Social Security Research, 2013). Furthermore, the age pattern of employment among women of reproductive age has been changing since the 1970s. The labor force participation rate of women aged 15–19 years has been declining steadily owing to increasing advancement to higher educational institutions and the rate of women aged 20–24 years has remained at roughly 70% throughout the postwar years, the labor force participation rates among women at the peak reproductive ages of 25–34 years increased sharply between 1975 and 2010: from 44 to 70% among women aged 25–29 years; and from 43 to 62% among women aged 30 to 34 years. Although the labor force participation rate among women at the peak childbearing ages is still lower than those of women in the younger and older ages thus preserving the well-known M-shaped age pattern of women's employment in the country, it has become much less notable since the mid-1970s. Although not as dramatically as among women aged 25–34 years, the labor force participation rate of women in their late thirties and forties also rose substantially during the same period. Hence, although Japanese women still tend to stop working during their peak childbearing and child-rearing years, such a tendency is weakening considerably in the recent decades.

In Korea, employment of women in their peak childbearing years began to increase precipitously in the 1980s. While the labor force participation among women aged 25–29 years had been stable at roughly 30% during the 1960s and the 1970s, it rose from 32% in 1980 to 68% in 2010 (Statistics Korea, 2011; Tsuya, 1991). The corresponding rate among women aged 30–34 years also increased from 41 to 56%, reaching levels similar to those of older women. The labor force participation rate in 2010 was 55% among women aged 35 to 39, and 62% among women aged 40–44 years. Consequently, the once notable M-shaped age pattern of women's employment has largely disappeared in Korea by 2010.

Unlike in Japan and Korea, there has been no M-shaped age pattern of female employment in postwar Taiwan, and the labor force participation rates of women of reproductive age have been increasing steadily since the mid-1950s, except for women aged 15–24 years whose employment rate decreased during the last few decades due to rising educational attainment. On the other hand, the labor force participation rose dramatically and steadily among women at peak childbearing and child-rearing ages. From 1966 to 2010, the labor force participation rate rose fourfold – from 21 to 84% – among women aged 25–29 years, almost four times from 19 to 77% among women aged 30–34 years, and three and half times from 21 to 74% among women aged 35–39 years (Directorate-General of Budget, Accounting and Statistics, 2012b; Tsuya, 1991).

Concluding Remarks

Japan, Korea, and Taiwan all went through rapid fertility transitions from high to the replacement level in the earlier postwar decades, followed by further and ongoing declines to well-below replacement levels of childbearing in the recent decades. While the earlier fertility transitions in these East Asian countries were due mainly to reduction of fertility among married women through deliberate control of their family size using contraception and induced abortion, the more recent transitions to very low levels of fertility were due largely to dramatic decreases in marriage among women at peak reproductive ages. These decreases in marriage among Japanese, Korean, and Taiwanese women at peak childbearing ages were associated with rising educational attainment among young women as well as increasing and prolonging paid employment among women at peak childbearing and child-rearing ages in the larger context of rapid economic development.

Although the timing, tempo, and scale of the fertility transitions are somewhat different among these three East Asian countries, dramatic reductions in their fertility to well-below replacement levels has resulted in or will soon bring about extremely rapid population aging and foreshadow dramatic population decline. With the proportion of population aged 65 and above years at 23% in 2010, Japan is currently the most aged country in the world, and its population aging is estimated to proceed further with the proportion of the elderly reaching 40% in 2060, according to the country's latest official population projection (based on the medium variants of fertility and mortality) (National Institute of Population and Social Security Research, 2013). Japan's population also started to decline in 2005, and the pace of the decline is projected to accelerate during the next half century. Japan's population size is estimated to shrink by almost one-third from approximately 128 million in 2010 to 87 million in 2060.

Although the populations of Korea and Taiwan are not yet as aged as Japan's, they are expected to age much more rapidly. In Korea, the proportion of population aged 65 years and above is projected to increase nearly four times from 11% in 2010 to 40% in 2060 (Statistics Korea, 2013) and, similarly, the proportion of the elderly in Taiwan is estimated to rise almost fourfold from 11% in 2010 to 39% in 2060 (Directorate-General of Budget, Accounting and Statistics, 2012a). While their population sizes are projected to grow slightly until the late 2020s to early 2030s, the populations of Korea and Taiwan are expected to shrink thereafter. Korea's population is estimated to edge up from around 49 million in 2010 to 52 million in 2030, followed by a sharp decline to around 44 million in 2060. Taiwan's population is projected to be stable at around 23 to 24 million between 2010 and 2030, and then to take a notable downturn to around 19 million in 2060.

Fertility Transition: Economic Explanations

Paul T Schultz, Yale University, New Haven, CT, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Economic explanations for the fertility transition focus on the increase in wage premiums for better educated workers, especially for women, that encourage them to obtain more schooling and participate more of their time outside of the household. The private opportunity cost of mother's time employed in child-rearing has increased more rapidly than the cost of many other less time-intensive consumption goods and productive activities. These developments motivate parents to find less costly substitutes for additional births, and it is hypothesized that investments in the health, nutrition, and education of their children are such substitutes for more births. Empirical studies of individuals and countries offer a bridge connecting growth in labor productivity associated with the Industrial Revolution and the Fertility Transition. Yet the identification of well-measured forces outside of the family that set into motion these changes in family behavior remain controversial. What precisely increased the productivity of women's time outside of the home, made women's schooling more valuable and added to their life cycle earnings, and increased their children's survival? Variation in fertility has not been explained by a single widely accepted conceptual framework, in part because historical data over time on the forces outside the control of the family, which might drive these changes in reproductive behavior, are difficult to measure. Productive returns to schooling, for example, are rarely quantified before the start of the twentieth century, and even then wage returns are inferred for samples of individuals who report monetized labor earnings, the productive characteristics of those engaged in home production, and self-employment are expected to differ from those of wage earners. The underlying mechanism causing better educated workers to be more productive than their peers can be plausibly explained, but not confidently tested, such as the growing capital–labor intensity of production, or changes in the composition of output from industrial products to services, or increases in the relative price of goods and services that more educated females produce, or technical change that is biased toward employing better educated workers (Kuznets, 1966; Galor and Weil, 2000). States have also become more involved in the regulation of trade and industry, and the repercussions of social welfare policies on the family reinforce the incentives to reduce fertility. This article describes different lines of historical research mostly on the European demographic transition of the nineteenth century, and research findings from the study of low-income countries in the last 50 years.

Understanding the Economic Determinants of the Fertility

The collection of representative household surveys in the twentieth century and the reconstitution of community records of marriages, births, and deaths in earlier periods have allowed one to match at the individual level how marriage, fertility, schooling, economic activities, family wealth and income evolve together, and may help to account for how these forms of life cycle behavior at the family level are coordinated. Unexplained variations in these family behaviors are nonetheless likely to be interdependent since they are constrained by a family's shared endowments, market opportunities, and uncertainty introduced by weather, droughts, epidemics, etc. One approach to quantifying the external determinants of fertility is to measure and analyze the effects of shocks from outside of the family as a force that perturbs exogenously the family's environment and opportunities, and thereby simulates how family behavior responds to some key outcomes, and suggests how historical forces might affect fertility, such as changes in productive technology and trade that are expected to impact family outcomes during the fertility transition. One such independent biological event is for a woman in the first pregnancy to have twins, presumably an increase in her numbers of potential births that can be interpreted as a 'natural experiment' from which to estimate from individual data how this unplanned variation in the number of children affects the quality of subsequent children, such as their school attainment (Rosenzweig and Wolpin, 1980). Twins also provide a means for estimating how the resulting variation in family size affects women's commitments to the labor force, and affects the transfers a mother can expect to receive from her children in her old age, as recently documented in large panel surveys and censuses from China and Indonesia (Oliveira, 2013).

At the end of the nineteenth century, social legislation was first enacted for pensions for older workers, and a safety net established for the disabled, unemployed, and widowed that are hypothesized to have reduced the need for parents to have their own children to support them in old age. At about the same time, communities and governments began to coordinate tax support for public compulsory schools, child health programs, and restrictions on child labor. These public subsidies for child schooling and health are likely to affect private returns to these forms of child human capital investments and encouraged parents to substitute them for having more births. However, the inverse correlation between these important forms of human capital investments per child and the number of children parents have is not necessarily a causal effect in one direction or the other, unless some outside force, such as twins, is specified that would identify a plausible causal behavioral effect in only one direction.

Economic Approaches to the Fertility Transition

With the establishment of modern economic growth, fertility has tended to decline; first across high-income countries starting largely in the last quarter of the nineteenth century, and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31076-5

then even more rapidly across most low-income countries in the last quarter of the twentieth century (Kuznets, 1966; Schultz, 1981, 1997). Economic models of the allocation of time and wealth of families among production and consumption activities suggest several hypotheses linking changes in the economic environment in which people live to their reproductive demands and fertility (Becker, 1960; Mincer, 1963; Schultz, 1974). Empirical counterparts for the price, income, and environmental constraints on people's fertility choices have been used to explain aspects of fertility and other related outcomes of the family, strengthening the view that this household demand model sheds light on the determinants of the historic fertility transition (Schultz, 1974; Becker, 1981).

This economic approach to fertility determinants has been criticized by those who believe that fertility does not systematically adapt to changing economic conditions (Cleland and Wilson, 1987). The proposed alternative to the economic approach, that is called 'ideational change,' emphasizes social interactions and cultural barriers to the transmission of knowledge of birth control technology, but has not evolved to a form that it can be empirically distinguished from the predictions of the economic framework. However, research that seeks to quantify the interactive role of couples and household coresidents, or even peers, neighbors, or members of social networks can postulate in cooperative and non-cooperative game strategies within these groups of individuals. But because these groups are generally self-selected, it is complex to specify the factors that affect the formation of the group and do not also affect the behavior of individuals who decide to join such groups (Heckman, 1979; Manski, 1995). There is an active debate on how to apply the economic framework and to exploit statistically cross-sectional and time series variation in fertility to improve our understanding of these more diffuse determinants of fertility (e.g., Schultz, 1997).

There is a fundamental methodological divide between researchers who want to describe a 'structural model' that involves interactions between choices made at the household level, including those choices spanning an adult's lifetime, such as between a woman's fertility, marriage, and labor force history, and those who investigate a 'reduced form model' where only outside constraints on household choice are considered as potential explanatory variables, or commonly, market prices, predetermined income sources, technologies, and the physical–biological environment. It is widely recognized that the associations between lifetime choices represent more (or less) than a simple causal effect of one choice on another. Covariations between family choices embody possible effects transmitted in both directions, effects of unobserved factors that impact both outcomes, and heterogeneity due to latent differences among families, in individual constraints or preferences (Schultz, 1981). Identification restrictions are generally required to be estimated from nonexperimental data, the critical parameters to 'structural models,' and therefore the empirical conclusions drawn from them are often controversial, because they depend on untested and debatable modeling specifications (Manski, 1995). The intuitive appeal of studies of the consequences of 'twinning' is that they rely on a demographic treatment that is not readily controlled by the family, at least not until recent times.

The alternative approach is to estimate fertility as a function of explanatory variables that are not family choice variables or are not likely to be impacted by unobserved factors that could also affect fertility. By delimiting the potential list of explanatory variables, these 'reduced form' relationships represent a summation of the direct effect of the environmentally fixed constraints on the couple's fertility, plus the possible indirect effect of the same constraints on fertility that operate through the modification of other choice variables, such as the woman's age at marriage, extent of labor force activity outside of her home, sexual behavior, and contraceptive choice, etc. The limitation of reduced form estimates is that they do not necessarily clarify the mechanism by which the constraints impact fertility, for example, through the timing of marriage, or the adoption within marriage of various so-called 'natural' or 'unnatural' forms of birth control. The strength of reduced form estimates is that they try to provide an unbiased approximation for the total effect of the constraint on fertility, which is often a central concern of the social scientist, demographic forecaster, or policy maker.

Some historical demographers assign special importance to the moment when married women begin to restrict their birth rates in response to their prior number of births, or surviving children (Coale and Watkins, 1986). Although this may be a well-defined and interesting threshold that predicts the onset of the long-term decline in fertility in certain European populations, other populations may adopt other mechanisms to reach their changing reproductive goals, such as a change in median age at marriage (i.e., Malthus' preventive check), an increase in celibacy or the proportion who never marry in a birth cohort, an increase in the spacing of births within marriage, as may be evident in Africa today (Caldwell et al., 1992; Shapiro and Tabashe, 2003), or a change in nonmarital (illegitimate) fertility. Even in northern Europe, standard measures of the emergence of parity-specific fertility control within marriages are not precisely defined by existing data (Craft, 1989; Bengtsson and Dribe, 2006; Guinnane et al., 1994). Thus, economist generally focus on cohort fertility such as the number of children ever born, and do not single out one component, such as duration-specific marital fertility, that implicitly presumes the timing of entry into marriage is unrelated to reproductive goals or subsequent lifetime behavior of the couple. Because many studies of the fertility transition mechanically hold constant the age at marriage or the age composition of married women, to estimate what is then interpreted as the behavioral determinants of fertility, this methodology explicitly assumes that age at marriage is not in part a choice that could be responding to economic determinants of desired lifetime fertility.

Stages of the Demographic Transition

The 'demographic transition' refers to a sequence of three periods. In the first period, fertility and mortality rates are high and mortality tends to be highly variable, with population growth fluctuating widely about a moderate long-run trend of

growth or decline. Short-run responses in fertility (and mortality) can be attributed to cycles in weather, harvests, epidemics, or possibly to other exogenous variables, and the analysis of these shocks with time series statistical methods, such as vector-autoregression. In the second period, age-specific mortality rates decrease gradually, raising life expectancy at birth from 30–35 years in preindustrial Europe, to 70–80 years today in the high-income countries, and from 25–30 years in the low-income countries in the 1920s, to levels which today range from about 45–75, excluding countries ravaged by war or the onset of the AIDS epidemic. This second period is one of accelerating population growth, which some observers such as Malthus attributed to improved food supplies, and more specifically to the effects of nutrition on mortality, often initiated by technical progress in agriculture, followed by improved industrial productivity, and advances in transportation and communication, or the opening of the national economy to international trade (Fogel, 2004). A free press capable of publicizing food shortfalls and imminent famines has also been proposed as an institutional arrangement in the twentieth century that further mitigated excess mortality in the wake of periodic droughts and potential famines. Improvements in private and public health technologies are assigned an important role in reducing mortality, but some scholars argue that medical care was not very important in determining life expectancy before the start of the twentieth century with the introduction of antibacterials (sulfanilamide and penicillin) after the 1930s (Fogel, 2004).

In the third period of the transition, the secular decline in fertility begins, after which the number of births per woman falls by more than half, from five or six to about two, in the high-income countries, and from six to eight to about two or three in most low-income countries. Demographic experts conclude that when high-fertility levels have declined by more than 10%, they are not expected to rise again on a sustained basis (National Research Council, 2000). Medium-term swings in fertility are nonetheless distinguished from secular time series trends, occurring in response to major business cycles (e.g., the Great Depression followed by the post-World War II baby boom), wars, and economic shocks due to fundamental institutional changes, as occurred during the transition from centrally planned to market-oriented economies in the 1990s in eastern Europe and Russia, or in Iran after its Islamic Revolution, or during economic reversals in sub-Saharan Africa.

Economic Determinants of the Fertility Transition

Notestein (1945) described the early dimensions of the demographic transition, and speculated on the economic pressures, which he expected to reduce fertility in the low-income world: rising cost of children in urban life, individualistic promotion of child health and education. Economic models of a lifetime fertility choice emphasize different facets of this decision process, but the trade-off between quantity of children and their quality (i.e., education and health) has become a central theme (Becker, 1960, 1981; Schultz, 1981). Because women's time devoted to childcare is a large fraction of the modern private (opportunity) cost of fertility, her allocation of time is treated as jointly determined with fertility. Many cross-sectional and a few time series studies have related statistically this constraint to fertility outcomes.

A couple's lifetime wealth (endowments of human capital and nonhuman capital) is expected to increase with modern economic growth, and to encourage parents to demand more children, if the relative costs and functions of children did not change (Becker, 1960; Schultz, 1981). However, for reasons discussed below, the opportunity cost of children increased along with the cost of other goods and activities that complement the rearing of children, whereas the private price of some substitutes for children, such as old-age pensions and health care insurance, have been socialized and subsidized by governments. Marked improvements in the technology of birth control were developed in the 1950s, translating into the rapid diffusion of the pill (oral steroid contraceptive) and the interuterine device (IUD) to many parts of the world. The monetary and psychic cost and inconvenience (independent of coitus) of avoiding too many births was reduced, and should have reduced thereby the number of births. Family planning programs are not, clearly, a necessary condition for the occurrence of a fertility transition, because birth rates declined in some high-income countries without the benefit of new control technologies, or of public family planning extension activities designed to facilitate the adoption of birth control.

Finally, improvements in child health technology increased the proportion of births that survived to adulthood. Under two plausible assumptions these improvements in child survival would have fostered a homeostatic compensatory decline in fertility: (1) parent reproductive goals are defined primarily in terms of the number of surviving children parents have, rather than their number of births, and (2) these demands for survivors are highly price inelastic, such that the decline in child mortality, which reduces the opportunity costs for parents to produce a survivor, does not outweigh the substitution of parent resources into investments in higher child quality (Schultz, 1981). The actual expenditures parents commit to each of their children is not an indicator of the fixed private 'market price' of a child, but reflect the combination of the price of child inputs and also the parent's demand for child 'quality.' The market-determined prices of the inputs that households combine with their time to rear children are exogenous market prices. There is little consensus on which inputs to children are relevant, or how constant-quality input prices for children have changed, or whether they play a major role in the secular decline in fertility.

If Becker's (1960, 1981) hypothesis that quality and quantity of children are viewed by parents as substitutes is valid, and much of the variation in child quality is embodied in the education parents give their child, then the net decline in private price of schooling would affect positively the demand for quality and depress fertility. There is growing evidence in the twentieth century that wage returns to schooling increased in a widening circle of countries, and this can be viewed as a decline in the private price of schooling, which encourages well-informed parents and societies to invest more resources per child in the education of children. The increase in wage returns to schooling has been attributed to a technological bias

favoring skilled labor, or to the complementarity in production between the schooling of workers and the accumulating stock of technical knowledge available in the global economy.

Becker (1981) also assumes that the 'income effect' on the demand for child quality is a larger positive magnitude than the 'income effect' on the demand for child quantity. This might encourage parents to substitute further child quality for child quantity as their incomes increased from one generation to the next. This is an additional explanation for the anomalous fall in fertility in a period when per capita income was increasing and the private costs of rearing a surviving healthy child was falling.

The Labor Intensity of Children and Their Opportunity Cost

In the twentieth century, the fraction of national income paid out to labor has increased, despite the increase in capital employed per worker and the decrease in hours worked per year per worker (Kuznets, 1966; Fogel, 2004). Wage rates have grown relative to per capita income until the 1970s, implying that consumption activities that use more time of the consumer have become relatively more expensive over time. Children are thought to be a more 'time-intensive commodity' than the average of all consumption commodities. Therefore, the opportunity costs for household's to produce and benefit from a child have risen as parent wages have risen, offsetting some part of the increased demand for children that might have been otherwise attributed to rising per capita income (Mincer, 1963; Becker, 1965).

The household production–consumption model of family labor supply and resource allocation drew attention to gender specialization in household production, and to the 'female time-intensity' of children, thereby suggesting the woman's value of time could be a key component in the rising price of children (Mincer, 1963). In environments where the opportunity cost of female (i.e., mother's or childcare giver's) time is higher, fertility tends to be lower, other things equal (Schultz, 1981). The market wage available to women might thus be a useful 'opportunity price' variable for a child, and it has notably increased in the twentieth century at a time when fertility has fallen. But just as 'parental expenditures per child' do not represent a fixed market-determined price of a child, the woman's market wage does not represent a fixed price of a woman's lifetime input to child-rearing. First, the wage a woman receives in the labor force is affected by her prior job experience, which accumulates at different rates depending on her preferences among types of work and the allocation of her time. Consequently, a woman's wage is an endogenous choice variable closely linked to her lifetime allocation of time, which in turn is intimately related to her fertility decisions (Mincer, 1963).

A second problem with the woman's wage variable is that it is observed only for a self-selected fraction of women who work for a wage in the survey period, and this fraction has tended to rise over time in many populations, and to differ by socioeconomic strata within a population. It is possible that women who work for wages are those who receive an unexplained high-market wage offer, suggesting that the observed average wage of working women overstates the increasing value of time of an average woman. Conversely, women who are unusually productive in nonwage work, and thus are less likely to participate in the wage labor force, may still have an above average market-wage offer that they declined, in which case the observed average wage of working women would understate the increasing value of time of an average woman. Sample selection bias could distort the observed wage as a measure of the average value of women's time, and thus bias estimates of the 'woman's wage effect' on fertility (Heckman, 1979; Schultz, 1981).

The Value of Women's Time and the Cost of Children

If the observed wage of women is endogenously affected by women's life cycle behavior and cannot be treated as an exogenous market determinant of her life cycle fertility, women's wage cannot be directly included in a reduced form equation to predict its causal effect on fertility. A structural model may then be needed to estimate how productive opportunities for women to work outside of the home change, that are expected to lead to women's greater participation in the formal labor force, on-the-job advancements, raising productivity and wages that could reduce their fertility (e.g., Wanamaker, 2012). One approach to this problem is to employ the woman's schooling as an 'instrument' for her wage; schooling tends to be a good predictor of women's wages in the cross-section, just as schooling predicts men's wages. For most women, their human capital investment in schooling is completed before childbearing starts, and thus the schooling decision can be tentatively viewed as predetermined with respect to the choice of fertility; this is certainly plausible in nineteenth-century Europe, if not today in parts of sub-Saharan Africa where pregnancy may terminate the schooling of many girls. If the schooling decision is made by the child's parents, it may also be argued that the woman's schooling is relatively unaffected by her adult preferences between a labor market career and early fertility, in which case schooling may be a satisfactory 'instrument' for predicting the adult lifetime wage opportunities for adult women caused by exogenous forces outside the immediate control of adult women.

A second approach is to treat the structure of wages in the local labor market as exogenous from the individual's perspective, and the average local wage can be assumed independent of the individual woman's heterogeneity in her preferences between working outside the home and fertility. By averaging local individual wages at the community level and thus mitigating the correlation between idiosyncratic individual variation in preferences and wages, one can assess the fertility of women as a function of the regional average wage. But another source of bias could arise if general equilibrium pressures on the local wage due to unobserved regional conditions affected the local labor supply of women. Such an omitted variable that increases the labor supplied by women in a region should, other things equal, depress the market-clearing wage women receive in that locality, and could thereby boost fertility through the effects on the opportunity price of children. Consequently, such regional-omitted labor supply variables could bias the estimated effect of woman's regional

wage on fertility, masking the theoretically expected negative impact of aggregate derived demand-induced variation in women's wages on fertility.

To deal with this regional-omitted variable problem a regional instrument for wages may be useful that shifts only the aggregate regional economy's demand for female labor (relative to the demand for male labor), and thereby affects the local wage available to women (relative to men), but is not otherwise expected to influence fertility. Variables of this form that shift the aggregate regional derived demand schedule for women's labor are additional candidates for use as an 'instrument' for women's wages. Several types of variables might serve this purpose. One such demand variable is the regional location of natural resources; a second would be the composition of industries, which could also be affected by location of resources and the transportation network; a third could rely on the local composition of agricultural crops that are most profitable in the local agro-climatic conditions and soils and lead to the engagement of different proportions of female and male workers; and a fourth would rely on changes over time in internationally determined export–import prices for crops or industrial commodities that have a distinctive gender labor intensity, such as cash crops produced by males in some areas, such as coffee in Kenya, or Cacao in Ghana and Cote d'Ivoire, or tea in India and China. Finally, longer term evolutions of productive technology, such as higher yielding agricultural varieties and livestock or mechanization that shift the demand for labor in agriculture between men and women. A few illustrative studies can show how derived demand determinants can affect the relative productivity of women's labor.

Coal mines employ mostly men, and communities dependent on coal mines for their livelihood tend to have relatively low wages for women. Historically, these coal communities in the UK, United States, and elsewhere report relatively high-fertility levels, other things being equal (Haines, 1979). In the northern provinces of Sweden where the price and quantity of timber exports increased at the end of the nineteenth century, men's wages increased relative to women's wages, and fertility remained high well into the twentieth century. By contrast, fertility in the southern provinces of Sweden declined after the 1860s, as women's wages increased relative to those of men, in response to higher prices for exports of livestock, dairy, and food manufactured products, which relied relatively heavily on female labor (Schultz, 1985).

Natural resource exports also strengthen government finances by providing an inelastic source of tax revenues, notably in the case of oil and mineral exports. If traditional elites capture the rents on such exports, other forms of direct personal taxation can be reduced, though government revenues may then be less often allocated to support social services such as public health and schooling. Oil and mineral exporting countries tend to have relatively low levels of female paid labor force participation, and high fertility, holding constant for other factors including per capita income, and religion (Schultz, 1994).

Labor economists have noted that in regions where the share of employment in certain industries, for example, the services, are relatively large, female labor force participation rates tend to be higher, other things being equal. The importance of part-time, less-skilled, and physically less-demanding jobs are often associated with a larger share of women in the labor force, and also with a rise in the women's wages relative to men's, and lower fertility, other things being equal. Changes in fertility over time can then be potentially explained by changes in factors external to the household sector that govern the expansion of paid employment opportunities in industries that hire a disproportionate share of women (or men). The international price of a country's output (terms of trade) is another externally determined factor driving domestic demand that affects the composition of output and possibly gender differences in wages (e.g., Schultz, 1985). However, these changes in relative prices and employment prospects by gender must be perceived by couples as a long-term trend that they need to incorporate into setting their lifetime reproductive goals. On the other hand, year to year fluctuations in the price of coffee, which may employ much female labor in Colombia in the 1960s, might not have a notable impact on long run expectations and thereby influence cohort completed fertility.

The European Fertility Transition and Low Income Countries

With the opening of the US Erie Canal in 1825 and the reduction of ocean transportation costs, the increased global supply of grain from the middle west and from southern Russia depressed grain prices in European markets. The United Kingdom repealed their 'corn laws' in 1846, and removed their prohibitive tariffs on grain, and this change in trade policy improved opportunities for industrialization in the UK by reducing the cost of food and tending to increase the real wage of workers in export sectors such as textiles, which were relatively female labor intensive (e.g., Craft, 1989; Galloway et al., 1994). Some European countries continued to protect domestic grain producers, such as France, whereas others adapted to low-cost grain such as Sweden, Denmark, and the Netherlands. Even within agriculture, the composition of crops can affect the productive opportunities of women relative to men and their relative wages. As noted earlier in Sweden, dairy products and the export of butter encouraged employment of women and raised locally women's wages, whereas the decline in prices of grains depressed the agricultural wages of men. But different climate and soils of the different provinces of Sweden intermediated where these trade-induced movements in commodity prices affected most directly women's relative wages and fertility. In southern Sweden where the dairy industry was concentrated, fertility first declined, whereas in northern Sweden where forestry dominated the economy, male wages increased relative to female. Higher real wages for men were related to younger childbearing, but not to a significant change in total fertility rates. About one-third of the 25% decline in total fertility rates for Sweden as a whole in the period from 1860 to 1910 can be attributed to trade-driven increases of women's wage opportunities, whereas the rest of the decline in Swedish fertility in this half century is associated with urbanization and the increase in child survival, under the assumption that these were exogenous

developments (Schultz, 1985). Swedish parish registry data also confirm region-specific responses of fertility of individual women to these movements in international trade prices (Madestam and Simeonova, 2013). The Princeton European Fertility Project that sought to account for the fertility transition in Europe focused on Census indicators of industrialization, and not on the realignment in the prices of food grains and other agricultural and industrial commodities that may have impacted employment opportunities for European women by agricultural region (Coale and Watkins, 1986).

Agricultural productivity of men and women also differ markedly in low-income countries, and these differences have been attributed to natural resources, climate, and technology and the domestication of crops and livestock (Boserup, 1970). For example, Lavy (1985) attributes regional differences in relative wages for men and women in Egyptian agriculture to the regional comparative advantages in wheat or cotton. Female labor is relatively less valuable in wheat cultivated with plow technology than in cotton where women are valuable as cultivators and harvesters, and fertility is accordingly higher in the wheat growing regions.

When Mao relaxed the requirement that all regions in China be self-sufficient in food, tea production revived in those areas where geography and climate favored tea cultivation. Women's wages tend to be higher relative to men's in areas of tea cultivation in many parts of the world, due presumably to women's comparative advantage in plucking tea. The gender ratio of surviving females to males in the 2000 Census of China from cohorts born after Mao's policy increased in traditional tea regions, as did the schooling of girls relative to boys, even when these regions are compared to regions that specialized in the cultivation of orchards rather than tea. Survival and schooling of girls improves relative to boys as a response to the shift in composition of crops toward the female labor intensive tea (Qian, 2008).

In Ghana, cultivation of tree crops engage disproportionately more male than female labor, whereas cereals, fruits, and vegetables employ a greater share of female labor, given the local reliance on 'hoe technology.' If the differences in climate, soils, and agricultural technology account for the choice of crops by region, and explain gender differences in employment and wages by region, these agroclimatic factors may be a neglected key to explain women's participation in the family labor force and their fertility (Schultz, 2013). Crop composition also appears to be a local determinant of the prevalence of polygyny in neighboring Cote d'Ivoire as it also affects the family productivity of female labor (Jacoby, 1995). These studies presume that sex-specific interregional migration does not arbitrage away these gender differences in local wages or labor productivity affected by agroclimatic advantages for growing specific crops. Sex-specific migration may be restrained, depending on the country, by ethnicity, language barriers, and the slow diffusion of crop-specific agricultural productive knowledge between regions, or in the previous case of tea in China, by the government's system of residential registration that restrains the movement of the rural population.

The fertility transition in Prussian Germany has also been analyzed by region from 1816 to 1910. When regional persistent or regional fixed effects are included in the analysis of a pooled times series of cross sections, strong partial effects of industrialization and urbanization are associated with declining fertility from 1850 to 1910 (Richards, 1977). A regional fixed-effect specification for fertility has been estimated for smaller administrative units of Prussia from 1875 to 1910, but female labor force participation rates are added to explain the change in fertility (Galloway et al., 1994). This measure of labor force participation of women is plausibly a decision made jointly with the timing of marriage and fertility, and therefore when women's participation in the formal labor force is included as though it were an exogenous control, it accounts for the largest fraction of the fertility variation across Prussia during its fertility transition. These estimates are likely to be subject to simultaneous equation bias and are difficult to interpret as causal evidence of the impact of industrialization.

County-level data from the Prussian Censuses of 1816, 1847, and 1867 have subsequently been studied and they suggest that before the onset of the general fertility transition, fertility is already inversely related to school enrollment rates (Becker et al., 2013). However, this early indication of a trade off between quantity and quality of children does not establish causation without an exogenous explanation for why there is variation across communities in their investment in public schools or willingness to effectively enforce compulsory schooling laws. One hypothesis has been advanced that concentration of land ownership diminishes the effective demand for schooling in rural areas, because large landlords do not support the public provision of schooling (Galor et al., 2009). Assuming the landed aristocracy preferred lower wage farm labor and not better educated workers, the degree of concentration of land ownership by county would diminish school building. School enrollment rates predicted by the county are 'instrumented' by land concentration, which are inversely related to early fertility declines. This logic is extended further by ordering the census variables for counties over time. Land inequality in 1816 is used as an instrument to explain lower county enrollment of girls in 1816, which is associated with higher fertility of older women in 1847 and 1867 (who are presumably less well educated). As a further consistency check, changes between censuses in these county-level variables are used to account for changes in female enrollment and fertility (Becker et al., 2013). Nonetheless, many of these investigations of Prussian fertility, as with the European Fertility Project, control for the timing or prevalence of marriage, and even for the labor force participation of women, which are undoubtedly jointly determined choices along with fertility.

The Global Advancement in Women's Schooling

Throughout the world the advance of women's schooling tends to be associated with lower fertility, especially when controls are included for men's schooling or per capita income or consumption. This empirical regularity is often interpreted as a consequence of the increased opportunity cost of children when educated women enjoy improved opportunities to work outside of the home. By the start of the twentieth century, the

gender gap in schooling in the United States had diminished, except for college education. But this gap remained substantial in most countries in southern and eastern Europe until after the World War I, and women's years of schooling attainment began to catch up to that of men in low-income countries mainly in the aftermath of World War II. This trend in female schooling has been particularly slow in rural parts of South Asia where the fertility transition has also been delayed compared with East and Southeast Asia or Latin America. The wages of women with an additional year of schooling tend to increase by at least the same percentage as they do for men, which implies as the gender absolute gap in years of schooling diminishes, women's wages tend to increase relative to men's wages, as is seen in many parts of the developing world (Schultz, 1995).

The factors that have triggered these differential trends in the schooling of women and men have received relatively little study, and are often attributed to prevailing customs, and not explained by local exogenous changes in endowments, economic growth, composition of output, or globalization. But whatever the role of preexisting conditions and policy reforms, the expansion of women's schooling closely parallels the decline in fertility across high- and low-income countries since 1960, at both national and individual levels. Indeed, changes in women's schooling accounts for the largest share of the changes in total fertility rates observed in low-income countries since 1960, and in Africa since 1980 (Schultz, 1994). Even in an environment where economic progress has been minimal since the 1960s – Kinshasa City in the Congo – the increasing rate of female education is the most obvious factor explaining different levels of fertility across the population, and accounting for the decline in fertility in the 1980s and 1990s (Shapiro and Tombashe, 2003).

However, educated women could have lower fertility for many reasons, in addition to the greater opportunity cost of their time in child-rearing. The social and intellectual advantages that educated women may enjoy could help them in deciphering, adopting, and using effectively, new and old forms of birth control, and thereby avoiding births they do not want.

Female schooling may also affect fertility through its impact on the risks of child mortality. Censuses and surveys after World War II have documented for dozens of countries that child survival rates tend to be about 5% higher for mothers who have completed an additional year of schooling (Schultz, 1981, 1997). The proportionate decline in fertility associated with women's schooling is nonetheless larger than the proportionate increase in their child survival rates. Better educated women thus have smaller numbers of surviving children, which implies better educated women contribute less to the overall intergenerational rate of population growth than do their less educated peers (Schultz, 1994).

Schooling of women is also closely related to their labor force participation outside of their family, holding constant for their husband's income or education (Schultz, 1981). Household models of production and consumption generally assume that family labor supply choices are coordinated or jointly determined by family members, and women's education is expected to affect not only lifetime fertility, but also the timing of marriage and the positive matching of the productive characteristics between husband and wife in the marriage 'market.' Within such a framework of family-coordinated decision-making, it is a challenge to assess empirically how one of these jointly determined life-cycle choices made by women affects another of their choices.

To decompose the variation in fertility into that which is associated with the proximate timing of marriage, marital fertility rates, and non-marital fertility rates is a descriptive accounting exercise, but should not be used to infer causal connections. These three demographic components are likely to be behaviorally interdependent, because unobserved characteristics of women and their environments are likely to influence all of these components. The goal of explaining the fertility transition requires clarification of what external environmental developments or shifts in policy trigger or restrain the timing of the fertility transition.

Conclusions

The equalization of schooling of women and men and the reduction in the relative gender gap in wages are linked to the quality–quantity trade-off that relates the investment of parents in their children's schooling and health and the decline in fertility. This empirical regularity appears to be an important bridge between the Industrial Revolution and the Fertility Transition (Notestein, 1945; Galor and Weil, 2000). However, to understand the origins and causal significance of this inverse association requires in addition the identification of factors external to the household and community that can be accurately measured and are plausible determinants of private demand for, or public supply of, schooling for women and men. In addition, this factor must not otherwise affect the private demand for births or the biological determinants of reproductive potential or the supply of births, if the data are to single out the mechanisms by which variation in society contributes to time trends in fertility.

Economic explanations for the fertility transition emphasize the increasing returns to schooling since the Industrial Revolution, especially for women, which has encouraged women to obtain more schooling relative to men, and drive the advancement in women's wages absolutely and relative to the wages of men. These general attributes of economic development are not equally evident in all countries. Declines in fertility have therefore proceeded quite unevenly, first across the high-income countries, and more recently across the low-income countries, but following a pattern of economic developments that has been widely quantified in household surveys and suggestively followed in cross-country comparisons. Two other economic factors linked to the fertility transition are the decline in mortality, particularly among children, and the increased value of employment opportunities available to women outside of their homes.

At an aggregate level, many states have simultaneously legislated socialized support systems to provide for the consumption requirements and medical care of the elderly, and for the school and health investment requirements of the young, which may have on balance reduced the private demand of parents for children. Conversely, the provision of these health and pension services by governments may ultimately reflect the revealed preferences of the population to rely

on the public sector rather than on their own children for such old-age supports. With modern economic growth associated with the emergence of new specialized jobs that rewards workers for their geographic mobility, the intergenerational family support network is placed at a growing disadvantage as a social insurance scheme that depends to a great extent on residential proximity of parent and child generations.

Abstract

In Latin America and the Caribbean, when mortality declined, the population growth rate rapidly increased, reaching levels of 3.4% per year, and then the onset of fertility initiated. Between the 1960s and 1970s, there was a shift in the trend of total fertility rates in all countries. The fertility decline has been attributed to diverse factors, such as improvement in women's education and their role in the labor force. A characteristic of the region is that contraceptive use increased, but remains low among young people.

Fertility Trends in Latin America and the Caribbean

The continued decline in mortality in Latin America and the Caribbean in the early twentieth century was not accompanied by an immediate decline in fertility in most countries. Latin American governments, concerned with the large population growth, fueled policies to reduce fertility. One of the ideas at the time was that in order to achieve the development of the countries, it was necessary to slow population growth. In contrast, others felt that economic and social development of the countries would lead to a reduction in fertility. In general, most countries initiated family planning policies to achieve a fertility decline, without waiting for the prerequisite of social development to take place. At that time, it was believed that in order to achieve development of the countries, it was necessary to slow population growth. In contrast, others felt that economic and social development of the countries would lead to a reduction in fertility. In general, most countries initiated family planning policies to achieve a fertility decline, without waiting for the prerequisite of social development to take place. Thus, for example, in the 1970s, Mexico presented an annual population growth rate of 3.4%, with a doubling time of 20 years (Ordorica, 2010, 2005), which led to the implementation of a vigorous contraception program. The 1960s and 1970s showed a shift in the trend of the global fertility rates of countries in the region, whose decline far exceeded expectations (CEPAL, 2012; see **Figure 1**). The demographic transition in Latin America occurred in an accelerated manner that led to drastic changes in the age structure of populations and gave way to the current aging process (Livi Bacci, 2012; Tapinos, 1990). The global fertility rate for the period 2005–10 was less than two children per woman in 11 of the 38 countries of Latin America and the Caribbean (United Nations, 2014; see **Figure 2**). Projections indicate that by 2025, half of the countries in the region will have a fertility rate

below replacement level (United Nations, 2014). Considering the information of recent surveys, it is also possible to argue that this projection will be exceeded in some countries, where the actual decline rate is even greater than expected. For example, the National Demographic and Health Survey of 2010 from Colombia reports a global fertility rate for that year of 2.1, while the UN projections have estimated a rate of 2.3 for the period 2010-15.

The factors related to fertility decline are diverse. On the one hand, social development in these countries, including steadily rising levels of women's education and their increased participation in the labor market, has played an important role. Also, the urbanization process experienced by Latin American countries has been important as it has led to improvements in access to health services and the expansion of mass media. With regards to schooling, between 2000 and 2007, the gross enrollment rate in secondary education increased from 83% to 89% and tertiary education accounted for the largest increase in comparison with other regions of the developing world, going from 23% to 34% between those years (Altbach et al., 2009). Barro and Lee (2010) estimate that in Latin America and the Caribbean, the average years of schooling of women over age 15 increased from 2.38 in 1950 to 8.21 in 2010. The participation of women in the labor market has also been growing over time. Around 1960, it was estimated that in some countries in the region, the labor participation rate of women aged 15–44 years was, on average, between 25% and 35% (Elizaga, 1974), by 2000 it was estimated to be 48%, and by 2010, 53% (World Bank, 2012). With regards to urbanization, it is noted that the percentage of urban population increased from 50% in the early 1960s to 79% by 2010 (World Bank, 2012). Births attended by medical personnel increased from 75% to 86% between 1990 and 2000, and as an example of the expansion of mass media, it has been estimated that the proportion of the Internet users in the region grew from zero in 1990 to 43% in 2012 (World Bank, 2012).

On the other hand, other aspects that have also played an important role in modifying fertility levels are the age at marriage (both formal and consensual union) and first birth, the increasing use of contraceptives, and changes in reproductive ideals. Although, as previously mentioned, all Latin American countries show a trend of decline in fertility rates, in some of them the rates have not declined at the same pace and level, as is the case in Guatemala, Haiti, and Bolivia (Plurinational State of) with 4.2, 3.6, and 3.5 children per woman, respectively. Additionally, there are differences within countries, with the lowest social strata having higher rates of fertility (Juarez et al., 2013a). Moreover, fertility rates have not had the same reduction in all age groups. One characteristic of Latin America and the Caribbean has been the slow pace of decline in adolescent fertility, which has become a specific research problem and policy focus (CEPAL, 2012). This contrasts with the evidence of a growth in the proportion of women who have not had any children up to age 30 or even at the end of the reproductive period (nulliparity), which shows a polarization in reproductive timing (CEPAL, 2012).

Proximate Determinates of Fertility

According to the approach of Davis and Blake (1956), there exists a set of factors, which have a direct impact on fertility.

Thus, changes in the age of sexual initiation may shorten or lengthen the time of exposure to risk of pregnancy, and its impact on fertility will depend on the use or the lack of usage of contraceptives. The situation in this respect is different in various countries of the region. In some, an early age at first intercourse has been observed, such as in Colombia, while in others it seems that, in general, there have been no major changes, as in the case of Mexico (Gayet et al., 2013). Compared with the experience of European countries, sexual onset in Latin America is earlier in most countries. The proportion of women aged 15–19 who have had sex in a group of countries with recent DHS surveys ranges from 10% in Guatemala to 50% in Colombia (Anderson et al., 2013). If the timing of sexual initiation, the onset of marriage, and age at first birth in countries with recent surveys are analyzed, it can be seen that the proportion of women aged 20–24 who started their sexual life before age 16 and before age 18 is considerable in Colombia and Guatemala (**Table 1**). In Colombia, sexual initiation is clearly separated from marriage, which is not so in other countries where fertility is still high, such as Guatemala. Before turning 18, 60.4% of women in Colombia had started sexual activity, while only 23% had married. In contrast, in Guatemala, 46.6% have had sex before age 18, compared to 37.9% who had married. The distances between the proportion of those sexually active and those married are markedly different. In turn, the proportion of those who had a child before that age is in some cases close to the proportion who had married, and quite large in countries like Guatemala and Honduras, where women who had a child before age 18 represent 27.1% and 22.2% of the women aged 20–24, respectively. This shows that there are different profiles between countries, but a common feature is early marriages and fertility, unlike what has been observed in European countries.

Table 1 Percentage of women aged 20–24 who have had first sexual intercourse, first marriage, and first birth before age 16 and age 18 in selected countries

% Of women 20–24	*Countries*					
	Colombia	*Mexico*	*Peru*	*Honduras*	*Bolivia*	*Guatemala*
Before age 16						
First sexual encounter	29.2	10.7	14.7	20.2	15.6	23.5
First marriage	10.0	6.5	7.1	15.1	7.6	19.1

Source: Juarez, F., Gayet, C., Mejía, G., 2013a. New and Old Paradigms on Fertility and Reproductive Health in Latin America. Paper presented in XXVII IUSSP International Population Conference, Busan, South Corea, 29.08.2013., estimated based on recent DHS and ENADID 2009 for Mexico.

The levels of modern methods of contraception use in the region are not low. For those countries with recent surveys, of women aged 15 to 24 who were married at the time of the interview, about 50% were using a modern method (**Figure 3**). Bolivia and Guatemala standout with lower levels and a significant proportion of women who were not using any method at all. In addition to the overall analysis of modern contraceptive methods, a key element is the type of method being used by women. In the literature, various studies have indicated that the use of methods that have daily intake or application, either before or during intercourse (e.g., pills, or barrier methods such as diaphragm and condoms), are less effective than long-term reversible methods. With the exception of Mexico, in the other countries surveyed the most used methods among married women aged 15–24 are injectables followed by tablets. Colombia stands out because young married women make greater use of long-term reversible methods than others (21% injections, implants 8.4%, and 6.8% IUD). Also in Mexico, the prevalence of IUD used among married women is notable (18.1%). Despite being young women, an important proportion has been sterilized in Colombia and Mexico, 7.0 and 4.2%, respectively (Juarez et al., 2013a).

An appropriate indicator to analyze the effectiveness of public policies is the unmet need for contraception. This number reflects the proportion of women who do not want

Married	Colombia	Mexico	Peru	Honduras	Bolivia	Guatemala
Modern	63.0	54.3	49.4	57.2	33.0	39.1

Source: Juarez, F., Gayet, C., Mejía, G., 2013a. New and Old Paradigms on Fertility and Reproductive Health in Latin America. Paper presented in XXVII IUSSP International Population Conference, Busan, South Corea, 29.08.2013., estimated based on recent DHS and ENADID 2009 for Mexico.

children and who are not using contraceptive methods to prevent pregnancy. In Mexico and Bolivia, 25% of young married women do not use the contraceptives they need (Table 2).

Sexually active, never-married young women are the ones who most require the use of contraception; however, their levels of contraceptive use are lower than among married women. For example, in the case of Colombia, 51.2% of never-married women aged 15–24 use modern contraception as compared to 63.0% of married women in the same age group. In Guatemala, 16.3% of never-married young women use modern methods, against 39.1% of married women. The case of Mexico stands out, a country of average development, where only 36.6% of young never-married women use modern methods compared to 54.3% of married women (Figure 3). One explanation is that health services are better prepared for married women, a situation that leads to young unmarried women having unintended pregnancies. The patterns of use of different modern contraceptives by young never-married women are quite different than that of those who are married. Condoms are the most used method in every country, followed by a much lower level of injections and pills (Juarez et al., 2013a). This widespread condom use occurs in these countries especially due to prevention programs of HIV/AIDS, and it should be noted that it is not the most effective method to prevent pregnancy, given that its use is not always consistent, which means that the responses to condom use would overestimate the use of modern methods.

Both, the lack of contraceptive use or the use of less effective methods, result in unplanned pregnancies and abortions. The level of abortions in Latin America and the Caribbean is the highest among the regions of the world, and most of the abortions are unsafe abortions (Sedgh et al., 2012). Estimates of induced abortion rates in some Latin American countries show that the level is even higher than 30 per 1000 women aged 15–44 years, much higher than that of some European countries (Sedgh et al., 2012; Juarez et al., 2013b). There exist a limited number of countries that have relatively reliable information on estimates of induced abortion by age of women. In a recent publication, it can be observed that in the case of Mexico, women of younger ages are those with the highest rates of abortion, reaching 55 abortions per 1000 women in the age group 20–24 years (Juarez et al., 2013b). In countries where fertility has declined and the motivation to have fewer children is strong, and contraceptive methods are not available or they are inconsistently used, the induced abortion rates are higher.

Focusing on Reproductive Rights

Finally, it is important to note that since a few decades ago the studies of fertility in Latin America and the Caribbean, as well as the provision of health services have been framed within a human rights perspective. Some countries since the 1980s and most of them later following the International Conference on Population and Development convened by the United Nations in Cairo in 1994, have since focused their contraception programs in the context of the right to reproductive health, leaving behind the exclusive emphasis on fertility in decline. The Plan of Action agreed at the conference included the right to universal access to reproductive health, in particular family planning and sexual health, with emphasis on equity and equality between the sexes. Also, a focus on reducing maternal and infant mortality was included. Furthermore, the proposed approach considers the economic, social, and cultural development for achievement of reproductive health. This perspective changed the study of fertility that in the past was only considered in terms of population growth and gave way to a broader conceptualization that included the measurement of unwanted fertility and unmet need for contraception in the context of the right to health. Countries have made progress in implementing the Action Plan, but there is still the challenge of putting into practice these rights, especially for the population not in union.

This article is a revision of the previous edition article by H.M. Yousif, volume 8, 5588–5593, © 2001, Elsevier Ltd.

Abstract

Fertility in the Middle East and North Africa declined by more than one-half in the period from 1960 to 2010, most rapidly in the two decades from the 1970s to the 1990s. At present seven of the 22 countries have fertility below replacement level (two births per woman), while the fertility rate exceeds three births per woman in six countries. Changes in marriage patterns have made an unusually large contribution to fertility decline in this region, roughly matching the contribution of improved birth control within marriage. Further decline will depend on future trends in marriage and the availability of the most effective methods of birth control (sterilization and induced abortion).

Introduction

The 22 countries considered here stretch from Western Sahara on the Atlantic coast of Africa to Iran in western Asia. The countries, and their estimated population sizes in 2010, are shown in Table 1. Nineteen of the 22 countries are commonly regarded as Arab states, as indicated by their membership in the Arab League. Some of these Arab countries contain substantial subgroups that are non-Arab according to criteria such as past and present culture (including language), historical patterns of migration and marriage, and/or self-identification. These include Berber population in Morocco and Algeria, Kurdish population in Iraq (and in the non-Arab countries of Iran and Turkey as well), and Asian labor migrants in the Persian Gulf states. Three of the countries are non-Arab: Iran, Israel, and Turkey. Note that Israel contains a large Arab minority population, however. With the exception of Israel, the majority of the population in all countries of the Middle East and North Africa is Muslim, but there are large Christian minorities in Egypt and in most of the countries in West Asia.

Table 1 Listing of countries and estimated population size (in millions) in 2010

Country	*Population*	*Country*	*Population*
North Africa		*West Asia*	
Algeria	37.1	Bahrain	1.2
Egypt	78.1	Iran	74.5
Libya	6.0	Iraq	31.0
Morocco	31.6	Israel	7.4
Sudan	35.6	Jordan	6.5
Tunisia	10.6	Kuwait	3.0
Western Sahara	0.5	Lebanon	4.3
		Oman	2.8
		Palestine	4.0
		Qatar	1.8
		Saudi Arabia	27.2
		Syria	21.5
		Turkey	72.1
		United Arab Emirates	8.4
		Yemen	22.8

In 2010, the total population of these 22 countries was estimated as 488 million persons, with almost one-half (46%) in the three demographic giants: Egypt, Iran, and Turkey. A large fraction of the population in this set of countries resides along the Mediterranean Sea in northern Africa and western Asia. There are also substantial population concentrations in Morocco on the Atlantic Ocean, Iraq in the Mesopotamian River plain, Turkey on the Anatolian plateau and eastern mountains, Iran in the plateaus and mountains of southwest Asia, and Saudi Arabia with population along both the Persian Gulf and the Red Sea. Throughout this geographic expanse annual rainfall is relatively light, and this explains the concentration of population along seas and rivers. This climatic factor also helps account for the high level of urbanization as rural settlements engaged in intensive agriculture is feasible on a large scale in only a few locations (Atlantic coast of North Africa, Nile River Valley, Mesopotamia, and Anatolian plateau).

Population dynamics in the Middle East and North Africa during the past century have been intertwined with political upheaval and uneven economic development (the discussion in this paragraph and the next draws on Courbage (1999), Fargues (1989), and Tabutin and Schoumaker (2005)). Most of the countries were subject to European imperial rule, either directly or through externally imposed local political regimes, beginning in the nineteenth century (Egypt) and continuing until a decade or so after World War II. The breakup of the Ottoman Empire at the end of World War I was especially consequential for the political history of Western Asia, with reverberations to the present (Iraq, Palestine, and Syria). The nationalism of the 1950s and 1960s resulted in generous social policies and programs in some countries (e.g., Egypt), with consequences for demographic behavior (fertility and migration). In the period since 2000, the region has experienced excessive civil strife – Iraq, Palestine, and Syria, with the strife in Palestine a continuation of conflict which began in the late 1940s. Note that the extreme civil strife in these countries spills over into neighboring countries, thereby affecting a large fraction of the population of the region (all three of the demographic giants have been directly affected by conflict in nearby countries). The period since 2010 has also witnessed historically significant internal political upheaval – the 'Arab Spring' – which began in Tunisia and has rippled through the region. The ultimate outcome of this upheaval is not yet

known, in particular the longer-term political influence of Islamist parties whose programs often include explicit pro-natalist prescriptions about family life.

As for economic development, the oil wealth of the Gulf States has had a profound impact on the entire region from the 1970s to the present. Non-oil-producing states have benefited from oil wealth via labor migration and tourism (i.e., holiday visits by Gulf State nationals). More generally, international migration is a dominant feature of the landscape throughout the region. This includes intra-regional labor migration to the Persian Gulf states and northward migration to western Europe, especially from the Maghreb countries in northern Africa (Morocco, Algeria, and Tunisia). The Middle East and North Africa have also participated in the global surge in formal schooling in recent decades. The high rates of women's secondary and university schooling in post-1980 birth cohorts represent a sharp departure from the past, with implications for marriage and childbearing.

Fertility Decline to Date

Overview

The level of fertility in these 22 countries in the period from the early 1950s to the present is summarized in Table 2. In this table the measure of fertility is the total fertility rate (TFR), which is the sum of age-specific fertility rates for women of reproductive age during the specified historical period. The TFR can be viewed as the average number of births at the termination of a woman's reproductive career, were this career characterized by childbearing at the rates observed during the historical period in question. That is, this is a lifetime total for a hypothetical (or 'synthetic') cohort, not an actual birth cohort of women (whose reproduction would extend over three historical decades).

In the early 1950s, when the region had largely recovered from the severe disruption caused by World War II, almost one-half of the countries in the region had TFRs which exceeded seven births per woman, and only two countries (Israel at 4.3 and Lebanon at 5.7) had TFRs below six births per woman. The average for the region was roughly seven births per woman. With the exception of Israel and Lebanon (TFR = 5.7), these can be regarded as pre-decline levels of fertility which had obtained, with slight variation, for many generations in the past. Available evidence indicates that pre-decline fertility in the Middle East and North Africa was higher than in other major regions, including other subregions of Asia, Sub-Saharan Africa, and Latin America and the Caribbean (Casterline, 2011; Rashad, 2000). This coincides with other quantitative and qualitative evidence of the fundamental pro-natalism of these societies in the past: relatively early and nearly universal marriage, short postpartum abstinence, and a high valuation placed on children and childbearing.

Six decades later in 2010–14, 16 of the 22 countries have TFRs below three births per woman, and the average fertility for the region is less than three births per woman, a decline in the level of fertility from the early 1950s of more than one-half. It is also evident from Table 1 that in the majority of countries the decline was concentrated in the two decade period from the early 1970s to the early 1990s, although to be sure further substantial decline has occurred from the early 1990s to the present. From a comparative perspective, fertility decline in this region was late to start; in the early 1970s, only five countries had TFRs below six births per woman (Bahrain, Egypt, Israel, Lebanon, and Turkey), and only two of these (Israel and Lebanon) were below five births per woman. Among major regions, only Sub-Saharan Africa experienced later onset of fertility decline. Through the 1960s and 1970s (and even into the 1980s), the Arab region appeared to be very reluctant to join in the gathering international movement toward lower levels of fertility, a fact frequently commented upon in the demographic literature and in policy forums; see Obermeyer (1992).

Once commenced, the declines proceeded rapidly – as summarized in Table 3. During the 1980s, when the pace of decline was most rapid, 11 of the 22 countries experienced a decline in their TFRs that exceeded 1.5 births per woman. Of the more populous countries, only Sudan and Yemen were not caught up in the rapid fertility decline in this period (indeed, Yemen's TFR is thought to have increased from the early 1970s to the early 1990s).

As of 2010–14, seven countries in the Middle East and North Africa have TFRs which are equal to or below replacement level of 2.1 births per woman; these countries are Bahrain, Iran, Lebanon, Qatar, Tunisia, Turkey, and United Arab Emirates. The low fertility in the Persian Gulf States (Bahrain, Qatar, and United Arab Emirates) is striking. At the other end of the spectrum, four countries retain TFRs above four births per woman; these countries are Iraq, Palestine, Sudan, and Yemen. Each of these countries has its own distinctive political and demographic history, but it is difficult to ignore the fact that three of the four (excepting Yemen) have experienced severe civil strife in recent decades. Political demography is more tangible in this region than most (Fargues, 2000; Khawaja, 2003).

Table 2 Distribution of country-level TFR by historical period

Fertility Decline by Country

There is considerable inter-country diversity in fertility decline – both the historical timing of onset and the pace of decline. This becomes clear from examining trajectories country-by-country. Fertility trends for 12 of the 22 countries are shown in Figures 1–3.

The fertility declines in North Africa (Figure 1) have several interesting features. The declines in Algeria and Morocco were rapid, especially in Algeria which from the mid-1970s to mid-1990s experienced one of the fastest declines on record (four-birth decline in merely 20 years). By comparison, the declines in Egypt and Sudan have proceeded more slowly, especially in Sudan which after 1990 has among the highest levels of fertility in the region. A final intriguing feature of Figure 1 is the increase in fertility observed in both Algeria and Morocco in the period after 2000; in both countries, the estimate for the most recent period (2010–14) has risen to nearly three births per woman after declining to around 2.5 births per woman in the early 2000s. This recent increase has surprised demographers, who fully expected fertility in both countries to continue downward to replacement level or below, following the pathway of most countries once rapid and sustained decline is underway. The Algerian case has been examined in some detail by Ouadah-Bedidi and Vallin (2013), who conclude that the rise is principally due to a fall in the average age at first marriage. Note that fertility increase in both countries preceded the political upheaval of the Arab Spring.

The same diversity is evident in the populous countries of West Asia. Iran experienced a spectacularly rapid fertility decline from the mid-1980s to the early 2000s, following a slight rise after the 1979 Revolution (the new government

Figure 2 Fertility decline in populous West Asian countries. Source: UN Population Division.

Figure 3 Fertility decline in select countries. Source: UN Population Division.

was initially explicitly pro-natalist). Abbasi-Shavazi et al. (2009) provide a comprehensive demographic portrait of this exceptional decline. Less remarked on is the substantial and relatively rapid fertility decline in Saudi Arabia in the period since 1980. In the most recent period fertility is still well above replacement level (the TFR estimate for 2010–14 is 2.7), so it remains uncertain whether fertility in Saudi Arabia will continue downward to replacement level (as has occurred in Iran and Turkey; the latter via slow and steady decline from the early 1950s to the present) or settle at a level above replacement or even increase (as has occurred in Algeria and Morocco). Iraq has experienced slow decline since the late 1960s; the UN estimates notwithstanding, its fertility patterns during the past decade of extreme civil unrest are murky due to disruption of demographic data collection.

Figure 3 shows four countries that are, in one respect or another, idiosyncratic. Israel has a majority Jewish population, and the majority of them are first- or second-generation emigrants from Europe or North America. Hence it is not surprising that Israel's level of fertility was markedly lower than other countries in the region through the 1950s and 1960s. What is perhaps unexpected is the stability of Israel's TFR at around three births per woman in the period from the 1980s to the present. This national-level TFR is an average of widely varying levels within the Israeli population, with sub-replacement fertility among the more secular and European segments offset by high fertility among Orthodox Jews (Fargues, 2000). Fertility in Palestine, by contrast, was quite high throughout the period from the early 1950s to the 1990s, and although it declined substantially after 1990 it remains moderately high up to the present (TFR = 4.0 in 2010–14) (Khawaja, 2003). Apart from Israel, Lebanon is usually regarded as the forerunner for fertility decline in this region, and its trajectory in **Figure 3** supports this. In the most recent period Lebanon's fertility is far below replacement (TFR = 1.5 in 2010–14), uniquely low among countries in this region. Finally, Tunisia is also often labeled as a fertility decline forerunner (Rashad, 2000), and this is indeed the case by comparison with its North African neighbors Algeria, Egypt, and Morocco (see **Figure 1**). But Tunisia's decline seems neither early nor rapid by comparison with several countries in West Asia (Iran, Lebanon, and Turkey).

Explanation

Demographic

A search for explanations for fertility decline in the Middle East and North Africa begins with demographic analysis of the direct determinants of fertility, namely sexual exposure and active birth control.

With regard to the former, because sexual activity in the region is confined to formal marital unions – probably less so than in the past but to a larger extent than in most other regions (Tabutin and Schoumaker, 2005) – the timing of first marriage and the ultimate proportion marrying have marked effects on fertility levels. Several analyses demonstrate convincingly that nuptiality change has made a substantial contribution to the fertility decline to date in this region (Rashad, 2000; Tabutin and Schoumaker, 2005). Considering the region as a whole, the nuptiality contribution has been on the order of one-half of the fertility decline, with the other one-half due to more effective birth control within marital unions. This breakdown varies across countries; in particular, the nuptiality contribution has been especially large in the Maghreb countries such as Algeria, Morocco, and Tunisia – where the nuptiality change has been most dramatic – and Lebanon as well, and the nuptiality contribution has been of lesser magnitude in Egypt, Iran, and Turkey.

The most direct evidence of the nuptiality change underway are declines in the proportion of women of reproductive age – especially under age 30 – who have ever married. Many of these declines are relatively recent, and hence it is too soon to determine whether the predominant phenomenon is delayed entrance to first marriage or an increase in celibacy (Rashad and Osman, 2003). This is an important distinction, not

necessarily from a mechanistic standpoint (lost reproductive exposure) but rather because of the societal implications, which in turn may indirectly bear on fertility. One might posit that an increase in celibacy is the more revolutionary of the two. If meaningful fractions of women (e.g., 10% or greater) remain unmarried through the reproductive years, almost necessarily this must force an acceptance of primary roles for adult women other than motherhood. To the extent such acceptance occurs, this could affect the formulation of childbearing goals of women in marital unions.

Recent demographic survey data show considerable cross-country variation in marriage patterns (Casterline, 2011). If one considers, for example, the percentage of women married under age 30, the percentage of those ever married at ages 20–24 ranges from 15% in Tunisia to nearly 60% in Palestine and Yemen, while at ages 25–29 the percentages range from below 50% in Algeria, Tunisia, and Lebanon to above 80% in Egypt and Yemen. The difference in reproductive exposure between, say, Algeria (16% married at ages 20–24) and Egypt (54% married at ages 20–24) is enormous. These are the ages at which reproductive unions tend to be most fertile.

Turning to the second major direct determinant of fertility, that is, active birth control, one of the noteworthy developments in the demography of this region in the period since 1960 has been the growing prevalence of contraception as a means of birth control (Tabutin and Schoumaker, 2005). The majority of women live in countries where at least one-half of the currently married women are using contraception (Casterline, 2011). Pursuing this in more detail, one can distinguish contraceptive methods according to their efficacy in preventing pregnancy. This investigation reveals several distinctive features of this region. First, ineffective 'traditional' methods are relatively prevalent in some countries. More specifically, withdrawal is popular in western Asia (Jordan, Lebanon, Syria, and Turkey), as has been evident in all fertility surveys in this subregion since the 1960s. Secondly, small percentages of women are sterilized, with the exception of several Gulf states (Oman and United Arab Emirates) and Iran. This is not surprising, as a common view among Arabs (most of whom are Sunni) is that sterilization is contrary to Islam. This is popular opinion, and not a view actively propounded by Islamic scholars (although it is the case that sterilization is rare in most Islamic countries). Recourse to sterilization to terminate childbearing once a desired number has been achieved is, therefore, regarded as an unappealing solution in most subgroups in this region. That leaves the inter-uterine device (IUD) and the oral contraceptive as the effective methods of choice; both are highly effective when used diligently but subject to error and deliberate discontinuation.

A further method of birth control is induced abortion. Induced abortion is legal under most circumstances in Israel, Tunisia, and Turkey, in limited circumstances (woman's physical and mental health) in most countries in the region, and only if the woman's life is endangered in a few countries (including Egypt and Iran) (United Nations Population Division, 2013b). Whatever the legal standing, there is a common assumption throughout these largely Islamic societies that induced abortion is contrary to Islam. There are no sound estimates of incidence (Tabutin and Schoumaker, 2005), but it can be assumed to be relatively low except in Iran, Lebanon, Tunisia, and Turkey. The incidence of induced abortion is probably highest for pregnancies of unmarried women, but these are also the most strenuously kept secret. In all likelihood, induced abortion has contributed less to fertility decline in the Middle East and North Africa than in other regions. Possibly increased demand for birth control will lead to far more reliance on induced abortion in the future; this possibility cannot be simply dismissed out of hand, especially given the increased availability of medical abortion (which can be procured from a pharmacy and administered privately at home). But to this point there is little indication that social norms against induced abortion are weakening, and, in the absence of concerted political efforts to legalize abortion, access to safe surgical abortion will remain difficult and costly.

Other Factors

Scholars have attributed fertility decline in this region to the constellation of factors posited to cause fertility decline in other major regions in the period since 1950: dramatic improvements in child survival, higher levels of formal schooling (especially for women), income growth and growth of secondary and tertiary sectors of the economy, and the emergence of norms of family life incompatible with high fertility. Existing scholarship contains no rigorous assessments of the relative weight of these and other hypothesized explanatory factors, but a number of scholars have rendered judgments on the basis of quantitative investigation (e.g., Rashad, 2000; Tabutin and Schoumaker, 2005).

From a comparative perspective, the causes of fertility decline in the Middle East and North Africa appear to be distinctive in several respects. First of all, adult women's participation in the formal labor market was relatively low in the past and up to the present is low from a comparative standpoint. This would seem to diminish the likely force of opportunity costs of childbearing, that is, the financial cost to the household of women foregoing income-generating economic activity in order to bear and raise children. Second, the establishment of expansive social welfare policies and programs in many countries in the region in the 1950s and 1960s created an unusual context for fertility decline. These programs included guaranteed employment in the public sector for persons with formal schooling credentials and subsidization of fuel and food. Directly and indirectly, these diffused the household-level cost of bearing and raising children. Arguably it was the weakening of the social welfare state beginning in the 1980s, as it became unaffordable and/or as the neoliberal economic policy came to dominate, which stimulated fertility decline in this region (see Courbage (1994) for the case of Syria).

There is dispute about the causal contribution to fertility decline of the provision of family planning services through public sector programs. Tunisia is often cited as an historically early demonstration of fertility reduction due in part to enhanced availability of good quality family planning services (Brown, 2007). Egypt has supported the largest and longest standing public-sector program in the region; Robinson and El-Zanaty (2006) give it much credit for the fertility decline to date, and Rashad and Eltigani (2005) somewhat less credit. From a demographic standpoint and as compared to other

countries in the region, a larger fraction of the Egyptian decline has been due to change in marital fertility than to change in nuptiality, a fact supportive of a relatively larger contribution of its family planning program. The Iranian decline too has been driven disproportionately by decline in marital fertility, and hence it is natural to credit effective provision of family planning services at the community level throughout Iran beginning in the late 1980s. But Abbasi-Shavazi et al. (2009) place more explanatory weight on shifts in the demand for children due to economic aspirations running ahead of economic opportunities. And the fertility decline in a few countries occurred in the absence of an active public-sector family planning program; Algeria is a notable instance (Ouadah-Bedidi and Vallin, 2013).

Three salient features of the demography of the Middle East and North Africa since the 1950s suggest a distinctive causal structure underlying its fertility decline. The first is the relatively large contribution to the fertility declines in most countries of postponement of entry to first marriage, that is, nuptiality change. This is evidence in support of the argument that increased formal schooling of women has been a decisive factor driving fertility decline. The second demographic feature is the relatively high rates of international migration. It is plausible that this has disrupted existing high-fertility regimes through multiple pathways, including transformation of household economics and economic aspirations, changes in intra-family power structure, and diffusion of new norms about family life. A third salient feature is the preexisting patriarchal character of the family system which directly and indirectly was strongly pro-natalist. Some scholars have argued that undermining this system was a prerequisite for fertility decline in these societies (Courbage and Todd, 2011; Fargues, 2005). For this reason, formal schooling of women may have assumed more importance as a cause of fertility in this region than elsewhere. Other factors noted above, including economic transformation and international migration, also may have served to weaken the patriarchal family system.

Prospects for Future Trends in Fertility

As of 2010–14, seven of 22 countries in the Middle East and North Africa have sub-replacement fertility, while six of the 22 countries have a TFR in excess of three births per woman. What does the evidence in hand suggest about prospects for future fertility change? This might consist of fertility increase in countries with the lowest fertility, and fertility decline in countries where fertility is well above replacement level.

Considering first the subset of countries with sub-replacement fertility, there is only one country with fertility far below replacement (i.e., TFR less than 1.8): Lebanon with a TFR of 1.5. Outside the Middle East and North Africa, the period since 2000 has witnessed substantial rebound in fertility in some countries with sub-replacement fertility, especially in northern Europe (most notably Sweden and the United Kingdom). But the more common pattern in western Europe, southern Europe, and East Asia has been rather a modest increase from TFRs far below replacement level (United Nations Population Division, 2013a). One might posit that Lebanon will adhere most closely to the Mediterranean pattern (Greece, Italy, and Spain) of sustained low fertility (although, to be sure, both Italy and Spain have recovered from TFRs well below 1.5). To this point – historical experience with fertility far below replacement is limited – there is no evidence that fertility below replacement level constitutes an unstable equilibrium.

More consequential is the future of fertility in those countries with recent TFRs in excess of three births per woman. Five of these six countries are in western Asia (Jordan, Iraq, Palestine, Syria, and Yemen), and the sixth is Sudan. Data from demographic surveys provide some basis for assessing the potential for further decline. These surveys routinely gather information on fertility desires. Over the decades, controversy has surrounded the measurement and interpretation of such data. But given that fertility is highly purposive, fertility desires are likely to be informative about fertility trends in the short-term, even recognizing the constraints which couples face in implementing their desires. Elsewhere (Casterline, 2011) the author has examined survey estimates of the level of unwanted fertility. These suggest that unwanted fertility is relatively common throughout the region – the fraction of unwanted births ranges between one-sixth (Lebanon) to one-third (Yemen) – and therefore fertility should decline further if women become more successful in avoiding unwanted births. At the same time, attitudinal data on fertility ideals makes clear that in most Middle East and North African countries younger cohorts of women (under age 30) continue to find families with three or more children appealing. Mean ideal number of children of 3.4 in Algeria, 3.1 in Lebanon, and 4.3 in Syria are especially striking, as each is substantially higher than the recent TFR. Almost no women choose zero or one child as their ideal. These and other attitudinal data are emphatic in documenting weak attachment to small-family ideals (i.e., two children or less) (Casterline, 2011). Other data reveal that most women recognize many advantages of stopping at two children and also perceive various costs of having three or more children. Even so, a large fraction of women – in some countries a plurality, even among the younger cohorts – desire to have three (or more) children. In short, while the attitudinal data reveal the prevalence of motivation in most countries to reduce fertility below existing levels, these data also provide no grounds for projecting that fertility will fall to two births per woman (or lower) in all countries in the region in the near future.

The behavioral factors that bear directly on fertility (see Section Demographic above) can also be examined for indications of the potential for further decline in fertility. There are, first of all, patterns of union formation. It was noted above that nuptiality change has made a substantial contribution to fertility decline in this region; does potential remain for further nuptiality change which would further depress fertility? Casterline (2011) examines the evidence and concludes that nuptiality change in the future has the potential to cause substantially more fertility decline in the region, especially in Egypt (most populous country in the region and characterized by relatively early marriage) and also in Morocco, Syria, and Yemen. And further nuptiality change does indeed seem likely; nuptiality change in the region appears to be driven by the (perceived) unaffordability of marriage, itself a function of heightened expectations about the material resources one

must bring to marriage (including the wedding itself) simultaneous with declines in economic opportunities for young adults (Rashad and Osman, 2003). Both could ease – the increase in expectations and the decline in economic opportunity – but this seems unlikely, at least in the short run.

The second behavioral factor which bears directly on fertility is active birth control. The heavy reliance on ineffective methods in some countries (see Section Demographic) leaves room for fertility reduction as a consequence of shifting the contraceptive method mix toward more effective methods. But the evident resistance to sterilization and induced abortion as a means of birth control, especially in the cluster of countries where fertility remains high, presents an obstacle to decline of fertility to two births per woman (or lower). An important unknown factor is whether medical induced abortion will become a common resolution of unintended pregnancies.

Finally, fertility prospects in Israel and Palestine resist conventional demographic analysis because of the unique confluence of political and demographic dynamics. It is reasonable to posit fertility decline in both countries, but it is not difficult to envision inter- and intra-country political developments which generate pressure toward maintenance of fertility levels substantially above replacement level.

Summing up this assessment of prospects for further decline in fertility, there are factors which facilitate and factors which hinder such further decline. Chief among the former is the potential for further nuptiality decline, and also the possibility of more recourse to medical abortion. Factors working against fertility decline include weak attachment to the two-child norm, and the fact that to this point neither sterilization nor surgical abortion are readily available as methods of birth control in those countries in the region which at present have fertility well above replacement level. Fertility rates at replacement level (or below) are almost never attained without heavy reliance on one or the other of these two methods of birth control.

Fertility Transition: South Asia

John Cleland, University of London, London, UK; and London School of Hygiene & Tropical Medicine, London, UK

Abstract

Between 1950 and 2010, fertility in South Asia fell from about 6 to 2.5 births per woman. In Sri Lanka and South India, this transition started in the late 1950s and childbearing has reached replacement level. By contrast, fertility in Pakistan changed little until the late 1980s and was still high at about 3.5 births in 2010. The most remarkable and unexpected development has been the steep declines in Bangladesh and Nepal, two of the poorest countries in the world. The diversity in the timing and speed of transition cannot be explained in terms of material prosperity. Progressive social policies – resulting in universal schooling, high life expectancy, and state welfare provision – offer a compelling explanation for the early declines in Sri Lanka and Kerala, and gender inequality has been advanced as the major barrier to fertility decline in north India and Pakistan. Vigorous state promotion of family planning has probably accelerated the pace of decline in Sri Lanka, India, and Nepal. In Bangladesh, the family planning program may have triggered the onset of reproductive change, while in Pakistan the program has been ineffective because of weak political support.

Between 1950 and 2010, fertility in South Asia fell from about six to less than three births per woman. In Sri Lanka and South India, this transition started in the late 1950s and childbearing has reached replacement level. By contrast, fertility in Pakistan changed little until the late 1980s and was still well above three births in 2010. The most remarkable and unexpected development has been the steep decline in Bangladesh, one of the poorest countries in the world. The diversity in the timing and speed of transition cannot be explained in terms of material prosperity. Progressive social policies – resulting in universal schooling, high life expectancy, and state welfare provision – offer a compelling explanation for the early declines in Sri Lanka and Kerala, and gender inequality has been advanced as the major barrier to fertility decline in north India, Nepal, and Pakistan. Vigorous state promotion of family planning has probably accelerated the pace of decline in Sri Lanka, India, and Nepal. In Bangladesh, the family planning program may have triggered the onset of reproductive change, while, in Pakistan, the program has been ineffective because of weak political support.

South Asia is defined here as the countries of former British India (India, Pakistan, and Bangladesh) plus Nepal and Sri Lanka. Their combined population was estimated to be 1600 million in the year 2010, equivalent to 23% of the global total. Fertility trends in this region are thus a crucially important determinant of future global population size. In this article, the course of fertility over the past 60 years will be described, attempts to explain changes in reproductive behavior will be reviewed, and prospects for future fertility decline assessed.

Data Sources

Though only Sri Lanka possesses a vital registration system with high coverage of births, there is nevertheless a relative abundance of demographic data sources in South Asia, including decennial censuses and large-scale single-round demographic surveys. In terms of regular demographic monitoring, the outstanding achievement of the region is India's Sample Registration System (SRS). The SRS has yielded annual demographic estimates for most states in India since the early 1970s.

The collection of accurate demographic data in South Asia is difficult and all national data sets are flawed to some extent. This has generated considerable controversy over the timing and magnitude of reproductive change in South Asia. Genuine uncertainty still exists over the details, particularly in Pakistan, where the quality of data is especially poor, but the broad contours of demographic change are well established.

Fertility Trends

The historic level of fertility in South Asia was probably similar to that of Europe and China, namely an average of 5.5–6.0 live births per woman, with fluctuations in the range of 4.5–6.5. Fertility rose during the 1950s and 1960s in some parts of the region, a reflection of declines in widowhood, changes in breastfeeding patterns and sexual behavior within marriage. Fertility peaked at around seven births per woman in Bangladesh and Pakistan in the 1970s but remained about one birth lower in the other three countries.

Sri Lanka was the forerunner of fertility transition (see Figure 1). The onset of decline dates back to the 1950s, and began largely in response to a rising age at marriage (Fernando, 1975). The first appreciable fall in national fertility in India occurred in the 1970s, in Pakistan and Bangladesh in the 1980s, and in Nepal in the early 1990s. Comparing the highest post-1950 fertility level with estimated levels between 2005 and 2010, childbearing has fallen most steeply in Bangladesh and Sri Lanka (66 and 59%, respectively), moderately in India and Nepal (about 50%), and least in Pakistan (about 45%). Undoubtedly, the most remarkable development has been the steep fall in fertility in Bangladesh, which remains one of the world's poorest countries.

These national trends mask geographical, ethnic, and socioeconomic variations in the timing of the onset and speed of reproductive change. In Bangladesh, fertility is and highest in

the eastern divisions of Sylhet and Chittagong Division, generally considered to be the most conservative but least poor parts of the country. In Nepal, fertility transition is more advanced in the hill zone than in the Terai (adjacent to India) or in the high-altitude mountain zone. The highest fertility in Pakistan is recorded in the least developed province, Baluchistan.

The diversity of reproductive trends in India is much greater (see Figure 2). In the northerly states of Bihar and Uttar Pradesh, which comprise nearly one quarter of the total population, demographic modernization has lagged far behind the rest of the country. Women's literacy, age at marriage, and life expectancy are all low; fertility has declined moderately but the level of childbearing was about four births per woman in 2005–06. By contrast, in the southern states of Kerala and Tamil Nadu fertility transition began early, probably in the late 1950s (Zachariah and Rajan 1997). According to the SRS, the level of childbearing had already fallen to about four births per woman by the early 1970s. Kerala reached replacement level fertility (i.e., the level required to maintain stability of population size in the long term) of a little above two births by 1988, eventually stabilizing at 1.8 births per woman. Replacement level was reached in Tamil Nadu in 1993. In the other two southern states, Andhra Pradesh and Karnataka, fertility is now at about replacement level.

Determinants of Transition

Direct Causes

South Asian transitions to lower fertility have been driven by two direct causes: a rise in marriage ages, thus reducing teenage childbearing; and increased family size limitation by contraception and abortion. There is less evidence of postponement of live births following marriage, or of changes in birth spacing. Contraception and abortion have been used to limit family size but not to delay first births, nor for birth spacing, except in Bangladesh. Reproduction is increasingly compressed within the age span of 20–30 years.

Throughout most of South Asia, early and universal marriage for women – with a wide gap of 5 to 8 years in the ages of brides and grooms – has been the historic norm. With the exceptions of Sri Lanka and parts of India (e.g., Kerala), the singulate mean age at marriage for women at the start of the twentieth century was about 13 years. (The singulate mean age

is calculated from census or survey data on proportions single by current age: for details see Hajnal, 1953; also Ní Bhrolcháin.) Marriage has remained universal but women's age at marriage has steadily increased. By the 1980s, the singulate mean ages were Bangladesh 16.6, India 18.3, Nepal 18.9, Pakistan 20.7, and Sri Lanka 24.4.

Marriage postponement probably accounts for 20 to 30% of the decline in total fertility in Pakistan and Sri Lanka but rather less in the other three countries. However, delayed marriage is not consciously motivated by a desire for smaller family sizes. The fundamental cause is a change in the marriage market. In a rapidly growing population, each age group is larger than the preceding older one and, in societies where women traditionally marry older men, this creates a surplus of marriageable women. It thus becomes more difficult and expensive for parents to find suitable bridegrooms for their daughters. Increasing secondary schooling for girls accentuates this upward pressure on marriage ages.

The major direct cause of the South Asia fertility transition is increased use of contraception and abortion. Abortion is believed to be commonly practiced in all five countries but its precise contribution to fertility decline is impossible to gauge with any confidence because in Sri Lanka, Pakistan and until recently in Nepal it is illegal, while in Bangladesh and India most terminations are unrecorded.

In contrast, trends in contraceptive practice have been monitored reliably. A very pronounced link exists between reported contraception and fertility. Around 2010, the percentage of married women in the reproductive age span who reported current use of a modern contraceptive method was in the narrow range of 44–53% with the exception of Pakistan at 19%. Highly effective methods are dominant. In India and Nepal, there is a heavy reliance on sterilization, mainly of women. In 2005, sterilization accounted for 68% of contraceptive protection in India, and the median age of sterilization of women was 25 years. In contrast, the great surge in contraceptive practice in Bangladesh since the late 1980s was dominated by increased use of hormonal methods.

Socioeconomic, Cultural, and Policy Influences

During the past 50 years, a fertility transition has spread across South Asia despite the variation in material, social, and cultural circumstances. Presumably some common underlying factor, or interrelated cluster of factors, accounts for the onset of transition over the same relatively short timescale. Such factors might include preceding mortality declines that have increased numbers of surviving children, or monetization of economies and growing aspirations for educating children and for material goods, all of which increase the cost of childbearing. The variations in the timing and speed of transition demand more context-specific explanations.

Population scientists disagree about the causes of change (*see* Fertility Transition: Cultural Explanations; Fertility Transition: Economic Explanations), and rather few widely accepted generalizations can be made. One of the few is that the fertility transition in the region is not primarily a response to rising living standards. Bangladesh remains one of the poorest countries in the world and the southern states of India have income levels that are below the national average. Indeed, some commentators have proposed that reproductive change has been driven by poverty rather than prosperity, though the microlevel evidence does not support this view: poorer families have more children than richer families.

Progressive social policies, resulting in universal schooling, high life expectancy, relative equality of incomes, and state welfare provision, offer a compelling explanation for the early transitions in Sri Lanka and Kerala. But this thesis applies less obviously to Tamil Nadu, where literacy and life expectancy are not exceptionally high, and is implausible in the case of Bangladesh.

Gender inequality has been a major explanatory theme (*see* Reproductive and Sexual Rights: Transnational Trends from a Global South Perspective). In an influential paper, Dyson and Moore (1983) interpreted the north–south gradient in Indian fertility in terms of the kinship structure. North India, Pakistan, and the Indo-Aryan majority in Nepal are part of a wider West Asian kinship system dominated by patrilineage. Its key characteristics include early exogamous marriage for women, a joint family structure, and an emphasis on purdah, which result in very limited autonomy for young wives and considerable pressure to produce sons. In northern Indian cities, the imperative to have a son is increasingly expressed in sex-selective abortion, an illegal practice but one that is difficult to suppress.

In contrast, southern India and Sri Lanka are part of a South and East Asian kinship system, where endogenous marriage and nuclear family are more prevalent, women's lives are less rigidly controlled, and preference for sons over daughters is less pronounced. According to Dyson and Moore this system, with its greater autonomy for women, is more amenable to demographic innovation, including the adoption of modern birth control. Bhat (1996) concluded that these elements of social structure and kinship account for some 30 to 50% of the north–south fertility difference in India. Possibly even more important is exposure to mass media, a result interpreted by Bhat as testimony to the powerful influence of Western ideas on reproductive behavior.

Considerable stress has also been laid on the role of education, particularly for women, as a facilitator of fertility transition. At the individual level, the reproductive behavior of unschooled women and those who have received primary schooling differs little, whereas those with secondary schooling invariably have fewer children. Yet the contextual influence of schooling may be more important than the impact of individual attainment. Women in Kerala and Tamil Nadu have lower fertility than those in Bihar and Uttar Pradesh, regardless of their length of schooling (see **Figure 2**). While it is widely accepted that high adult literacy has been conducive to reproductive change, it is also clearly not a precondition. In 1991, when Bangladesh was in the midst of rapid fertility decline, only 23% of adult women and 36% of men were literate.

The contribution of state family planning policies to the fertility transition is also controversial. All five countries have family planning policies with explicit demographic goals. All have offered financial incentives (or compensation payments) to individuals who agree to sterilization, and all have been criticized for coercive elements. In Sri Lanka, India, and Nepal, vigorous government promotion of family planning has probably accelerated fertility decline (see, for example,

Caldwell et al., 1982). In Bangladesh it may have been even more important. A well-known experiment in the Matlab district demonstrated that the appropriate provision of services could reduce fertility (Phillips et al., 1988) and it has been claimed that, while a preceding mortality decline was the underlying cause of the fertility transition, the family planning program was largely responsible for the timing and speed of change (Cleland et al., 1994). In Pakistan, the program has been largely ineffective because of weak political support.

Prospects for the Future

Bangladesh's fertility is projected to reach replacement level by 2015, Sri Lanka by 2020, India and Nepal by 2030, and Pakistan by 2040 (see **Figure 1**). The prospects for the continuation of past downward trends are good. Recent surveys indicate that at least 20% of births are unintended in Pakistan, Nepal, Bangladesh, and India. The United Nations Population Division expects fertility in the region to stabilize at 1.8 births. The crucial uncertainty about the future is whether or not fertility will fall further to the very low levels experienced in East Asia (*see* Fertility Transition: China; Fertility Transition: East Asia). In India, an appreciable proportion of men and women state a preference for one child only and the figure would be considerably higher in the absence of a desire for a son. However, sterilization, the dominant method, is a risky option for such couples and there is an obvious need for promotion of long-acting but reversible methods to facilitate this desire.

Abstract

On average, fertility in Southeast Asia is barely above replacement level and declining. However, the region includes countries with some of the highest and some of the lowest fertility levels in the world. Different political contexts have affected the timing of the fertility transition across the region. Also notable were differences in the pace of the fertility transition, between the predominantly Buddhist mainland and the predominantly Muslim or Catholic nations in insular Southeast Asia. While some nations are completing their fertility transition, others are facing the prospects of population aging and may soon undergo the second demographic transition.

Located east of the Indian subcontinent, south of China, and west of Melanesia (Figure 1), the 11 nations of Southeast Asia (SEA thereafter) have a combined population size estimated to be 619 million in 2013 – a more than threefold increase from the region's population of 168 million in 1950 (United Nations, 2013a). The average annual growth rate of 2.07% over this period outpaced the world population's growth rate and reflected a substantial difference between birth and death rates. Population growth has slowed dramatically in recent years and only remains positive due to population momentum – a relatively youthful age structure. The average period total fertility rate (TFR) for the region is barely above replacement level (2.13 in 2010–15, United Nations, 2013a).

However, the overall level and decline of SEA's fertility masks significant variations from country to country. The region includes countries with some of the highest and some of the lowest fertility levels in the world (Timor-Leste, third highest with 6.53, and Singapore, fourth lowest with 1.25 in 2005–10, United Nations, 2013b; Table S.12). SEA also includes nations with some of the world's most rapid fertility decline, for example, Vietnam from 1975–80 to 2005–10 (United Nations, 2013b; Table S.13) whereas others have experienced fertility lulls and even temporary increases during that same period (Cambodia, the Lao PDR, and Timor-Leste).

Demographic diversity is not entirely surprising in a region, which shares some common geographical, historical, religious,

Figure 1 Countries of Southeast Asia.

and cultural features, but also experienced quite varied patterns of colonial rule, political and economic systems, and development (Reid, 1988a, 1993; Wolters, 1999). Created originally in 1967 with only five member states, the Association of Southeast Asian Nations (ASEAN) today includes all of SEA except but the recently independent nation of Timor-Leste. Participation in ASEAN may eventually contribute to greater political and economic integration in a region divided by decades of cold war politics.

The main line of geographical and cultural division is typically drawn between the nations of mainland and insular SEA. (Although most of its population lives on the mainland, Malaysia also includes part of the island of Borneo, shared with Indonesia and Brunei Darussalam. Together with these two nations, Malaysia is generally classified in insular SEA with Singapore (the two only became separate nations in 1965), as well as Timor-Leste and the Philippines.) However, substantial diversity is also found within nations, such as between the different islands of large archipelagoes (Indonesia and the Philippines), or on the mainland, between densely populated lowlands and the relatively isolated uplands home to small ethnic minorities (Scott, 2009). Numerically larger groups of Chinese and Indian-origin have also been present throughout the region since the late nineteenth and early twentieth century (Cushman and Wang, 1988; Reid, 1996, 2001), especially in the major metropolitan areas of the region. Driving the new regional economies, these metropolitan areas are increasingly distinct – ethnically, economically, culturally, and demographically – from their (mostly rural) national populations. In 2000, the TFR in Bangkok was estimated at 1.16 children per woman, closer to Singapore's than to the national figure for Thailand at the time (1.81, Jones, 2009).

The extent of between- and within-nation diversity cannot be fully described here, but key features are highlighted because of their potential influence on the fertility transition. The principal religions present in SEA are (1) Buddhism, predominant on the mainland (Myanmar, Thailand, the Lao PDR, Cambodia, and Vietnam), (2) Catholicism, influential in the Philippines and Timor-Leste, and (3) Islam, the majority religion in Malaysia, Indonesia, and Brunei Darussalam, with significant minorities on the mainland (Cambodia and Thailand), in the Philippines, as well as in Singapore. Hinduism is the major religion in Bali (Indonesia) and among the ethnic Indian populations of Malaysia and Singapore, whereas Confucianism remains influence among ethnic Chinese communities found in metropolitan areas throughout the region. These different religious influences, and colonial histories have pulled Southeast peoples in different directions during the modern era, but they have not erased the distinctive cultural feature of SEA: women's relatively high status and economic autonomy (Reid, 1988b; Van Esterik, 1982). Age differences between spouses tend to be comparatively small (Casterline et al., 1986), currently between 2 and 4 years (United Nations, 2012). Although polygamy is allowed under Islam, it was never very common pattern in SEA (Reid, 1988b; Jones, 1994). Matrilocality is not rare in any Southeast Asian country and is often as common as patrilocality among the ethnic Malay populations in Malaysia and Indonesia, the Philippines, and in most mainland nations (Reid, 1988a; Jones, 1995). The major exceptions are Vietnam and ethnic Chinese populations throughout the region which express strong gender preference (Wongboonsin and Ruffolo, 1995; Guilmoto, 2012). Another common cultural pattern, especially among Buddhist societies is the moral obligation to repay parents for one's care in early life. The cultural expectation that children will support their elderly parents is widely shared in throughout the region (Croll, 2006).

A Demographic Overview

Five of SEA's 11 nations are now among the world's 25 largest countries, compared to only 2 in 1950. Indonesia, the fourth largest country in the world with 250 million people, is the region's "demographic giant," accounting for 40% of the region's population (**Table 1**). Close to 100 million people also live in the Philippines, and more than half of the population of SEA lives on these two archipelagoes (56.3%). The other three nations are in mainland SEA, Vietnam at the eastern

end and Thailand and Myanmar at the western end of the region. Together, these five nations account for more than 90% of the region's population.

SEA is densely populated. Compared to the world average of 51 people per squared kilometer, the regional average is 133 people per squared kilometer (**Table 1**), and five nations have density twice the world average or more. Besides the city-state of Singapore (7436), the Philippines (311), Vietnam, (268), Thailand (129), and Indonesia (126) are still predominantly rural countries. Dense rural settlements suggest demographic pressure on arable land that likely contributed to the growth of the large urban agglomerations that have developed in each of these nations. As of 2011, the population size of the urban agglomeration of Ho Chi Minh City (Vietnam) has reached 6.4 million inhabitants, Krung Thep (*Bangkok*, Thailand) 8.4 million, Jakarta (Indonesia) 9.8 million, and Manila (Philippines) 11.9 million (United Nations, 2011a). In 1975, Manila was already the region's largest urban agglomeration but with a population size of just 5.0 million.

As in many nations in the less developed regions (LDR) of the world, mortality has declined tremendously in the second half of the twentieth century (Heuveline, 1999). Three SEA nations (Cambodia, Myanmar, and Timor-Leste) have life expectancies at birth in the mid-60s, slightly below the contemporary LDR average of 67.0 (in 2010–15) (United Nations, 2013a) (**Table 1**). The estimates of life expectancy for the wealthiest nations, Singapore (81.3 years) and Brunei Darussalam (78.2 years), exceed the average longevity in the more developed regions (MDR, 76.9 years). Only slightly lower are estimates of life expectancy for Malaysia (74.6 years), Thailand (74.4 years), and Vietnam (75.5 years). These countries have experienced very rapid economic progress in recent decades. The diversity of mortality transitions in SEA nations exemplifies the varied "routes to low mortality" (Caldwell, 1986; Kuhn, 2010).

As for the transition to low fertility, Singapore was the region's forerunner, with a decline that started in the mid-twentieth century and proceeded with unprecedented speed – fertility had dropped below the replacement level by the late 1970s (Saw, 2005). In the rest of SEA, fertility rates seem stable or even increasing slightly in the 1950s. Such limited increases are fairly common across LDRs and usually indicate a decline in sexually transmitted diseases and subsequent infertility, rather than a fertility increase among fecund, married women. Fertility might have been increasing during the nineteenth century as well, as the colonial-period record, imperfect though it is, indicates an acceleration of population growth that may have preceded any significant improvement in health. While this fertility increase and its causes are still a matter of scholarly debate (Henley, 2011; Reid, 1992), the demographic picture becomes much clearer in the 1950s and reveals fertility rates in the range 5.5–7.4 children per woman that are fairly typical of LDR nations at the time (**Table 1**).

In mainland SEA, fertility levels did not decline significantly until the late 1960s (Thailand), the late 1970s (Myanmar and Vietnam), or even the late 1980s (Cambodia and the Lao PDR). When fertility rates begin to fall, however, after centuries of stability or slow increase, they declined rapidly. Replacement level was reached in less than 30 years after the onset of the decline in Thailand, Myanmar, and Vietnam (**Table 2**). While Thailand has come to exemplify a fast fertility decline in a relatively poor nation (e.g., Hirschman et al., 1994; Knodel et al., 1996), the decline in Myanmar and even more so in Vietnam from over seven children per woman in the early 1970s to replacement level before the century's end are equally impressive (Goodkind, 1995; Haughton, 1997). In Cambodia and the Lao PDR, civil unrest and warfare might have temporarily depressed fertility levels, but the actual transition did not start until after peace had returned, sometimes followed by

postcrisis "baby-boom" (Heuveline and Poch, 2007). However, at the current pace, these two nations are expected to reach replacement level fertility in less than 30 years after the onset of fertility decline. While different political contexts are likely to have affected the onset of fertility declines, all mainland SEA nations will likely share a fast transition to replacement fertility. Moreover, fertility declines have not stopped at replacement levels, and there is still no indication that the current estimates of the number of children per woman have stopped declining in Thailand (1.53), Myanmar (1.94), or Vietnam (1.75).

With the exception of Timor-Leste, which only recently won its independence, fertility began to decline in most of insular SEA from the early 1960s to the early 1970s. On the mainland at the time, only Thailand showed any sign of a fertility transition. However, no insular SEA nations had reached replacement fertility by 2010 (except Singapore of course). In spite of a population density almost three times the regional average, average fertility in the Philippines is still above three children per woman. At the current pace, the Philippine fertility transition may take over 60 years, more than twice the actual or projected duration in any of the mainland SEA nations. In spite of being wealthier, markedly more urbanized (71.3% vs 41.4%), and enjoying child mortality rates three times lower than average for the region, Malaysia's total fertility is still above 2.5 children per woman (G.W. Jones, 1990). As had been observed in Malaysia in the 1980s (Hirschman, 1986), the most recent data for Indonesia indicates a stall or even an increase in fertility from 2.27 in 2000 to 2.41 in 2010 (Badan Pusat Statistik, 2013). This casts doubts on the current projection that the fertility transition might be completed in 2010–15, which would have been the fastest in insular SEA besides Singapore, but would still have taken about 40 years from onset to replacement fertility.

Explanations of Fertility Transition in Southeast Asian Nations

Fertility transitions are typically driven by declines in marital fertility, and this has clearly been the dominant pattern in SEA (Retherford and Cho, 1973; Hirschman and Guest, 1990a). However, there have also been significant changes in marriage patterns in several Southeast Asian countries. The erosion of arranged marriages has led to declines in the proportion of married females at young ages and increases in the mean age at marriage among Muslims in Indonesia and Malaysia in particular (Leete, 1994; Jones, 1995; Hull, 2012; Jones and Gubhaju, 2012). The postponement of marriage was, however, a modest factor in shaping total fertility changes in SEA compared to changes in the behavior of couples after marriage. The gradual adoption of modern contraceptives appears to have played the crucial role in this decline of marital fertility (Hull et al., 1977; Freedman et al., 1981; Ross and Poedjastoeti, 1983; Knodel et al., 1987; Entwisle et al., 1997) in the 1970s through the 1990s. The recent changes in marital patterns, including significant proportions of never married women in their 30s may be a more consequential determinant of fertility in the coming years.

A growing consensus assigns to mortality change a central role in explaining the onset of the fertility transition (Hirschman, 1994; Mason, 1997; Cleland, 2001). The spectacular declines in child mortality, in particular, added strains on the family (Davis, 1963), but more generally, contributed to an acceleration of population growth in already densely populated areas. Pre-transitional fertility levels were lower in higher density areas in Indonesia (Hugo et al., 1987), higher in lower density frontier areas in Thailand (Vanlandingham and Hirschman, 2001) and increased after mortality-driven reduction in population density in Cambodia (Heuveline and Poch, 2007). Consistent with this interpretation, pre-1975 fertility declines are visible in the SEA nations with the lowest child mortality levels (Brunei Darussalam, Malaysia, Singapore) or with the highest population densities (Indonesia, Thailand, Philippines). The only exception to this generalization is Vietnam, but the transition likely delayed by the war there eventually outpaced transitions in the rest of the region.

In the classic formulation of the demographic transition theory (Notestein, 1953), mortality decline was assigned less of a central role, being held rather as one of the several dimensions of modernization, or even possibly a consequence thereof. The multidimensional development process, with rising levels of urbanization and education accompanying lower mortality rates may explain the early onset of the transition in Singapore. In the rest of the region, however, as in much of the LDR, mortality declines were achieved rapidly after World War II, ahead of any other sign of substantial modernization (in particular in Myanmar or Vietnam). In some countries, subsequent modernization likely played an accelerating role after the onset of fertility decline (Hirschman and Guest, 1990b; Gertler and Molyneaux, 1994; Hirschman et al., 1998). With the development of public education systems, parents cite the associated increase in the costs of childrearing as one of the factors influencing their decisions to have fewer children (e.g., Knodel et al., 1984). Some of the increase, however, originates less in the educational system than in the job market and the perception of an intensifying competition that leads to higher parental investments and eventually so-called "quantify/quality" trade-offs (Becker, 1991). Another crucial factor in the increasing costs of childrearing has been the opportunity costs of women's wages. Traditionally engaged in the formal economy, women have provided almost the entire workforce of delocalized factories in fast-expanding sectors like the garment industry.

While mortality, with or without other modernization factors, contributed to reduce the demand for children, family planning programs facilitated access to more efficient means to achieve smaller families. In Thailand, Indonesia, or Vietnam, the onset of fertility decline seems to occur very soon after family planning programs were set up (Ross and Poedjastoeti, 1983; Robinson and Rachapaetayakom, 1993; Haughton, 1997). These three nations still have the highest modern contraceptive prevalence rates in the region today (**Table 2**), and the effectiveness of their national programs was clearly a factor in their fertility reaching replacement levels or lower – in Vietnam in particular, with the introduction of a one–two child policy (Goodkind, 1995). Signs of a fertility decline were visible before the establishment of a national family

planning program in some countries, for example, in the Philippines, though by only a few years, and even more clearly in Myanmar (Herrin, 2007; Myint, 1991). In Cambodia, the Lao PDR, and Myanmar, modern contraceptive prevalence has increased in the first decade of the twenty-first century and now ranges from 34.9% to 45.7%. These contraceptive prevalence rates, though high by historical patterns, are actually lower than the levels usually associated with their fertility: Laos has a prevalence rate of 55.2% and a TFR of 2.57 children per woman. Other than contraceptive use, potential factors contributing to this low fertility includes spousal separation due to temporary work-related migration and voluntary abstinence.

Overall, the fertility transition is relatively advanced in SEA and the region's cultural context has typically been considered favorable to the fertility transition (e.g., relatively high-female autonomy). Contrasting nations within SEA, however, one can hardly overlook the religious dimension. In the predominantly Catholic Philippines, the transition has been very gradual, arguably more typical of Latin American nations. As noted earlier, the transition in predominantly Muslim Indonesia and Malaysia have proceeded unevenly, with some temporary lulls or possibly reversals. The transitions in predominantly Buddhist mainland SEA started later, proceeded faster, and to date, without interruption until well below replacement level. The uneven transition in multi-ethnic Malaysia and Indonesia might reflect fertility transitions proceeding at different paces among different communities – differences that might be related to government policies (Govindasamy and DaVanzo, 1992). Although their small population sizes often makes them invisible even in disaggregated, subnational data, the limited evidence on the various highland populations in the region suggests that their fertility remains high and stands out from the general transition in the region (Gray et al., 2005).

Completing the First, Starting a Second Demographic Transition?

Fertility is currently below replacement in 6 of the 11 SEA nations. Recent trends suggest that fertility in these nations is very likely to remain below replacement in the next couple of decades (**Table 2**). Concerns over high density and fast growing populations may soon be replaced by concerns over rapidly aging populations that may even experience absolute decline in the coming years. The median age in Thailand is projected to reach 51.1 years by 2050, which would make it one of the 10 oldest in the world (United Nations, 2013a).

Singapore has tried to increase fertility (Saw, 2005: Chapters 11–13), but as elsewhere in the world, their pro-marriage and pro-natalist policies only had a limited impact (Yap, 1995) and failed to durably and substantially raise fertility (Jones, 2012). In contrast to Europe, changes in the timing of fertility have had little impact on period fertility rates in SEA (Chuan, 2010). In Europe, the postponement of fertility has been a major reason for the ultra-low levels of fertility in recent years. Since fertility postponement cannot continue indefinitely, this downward trend appears to have run its course and period fertility measures are inching back up (Goldstein et al., 2009). By contrast, in SEA, mean ages at marriage remain below 25 in most nations (SMAM (Singulate Mean Age at Marriage), **Table 2**), and fertility rates have fallen even more after age 35 than below age 35 (e.g., Thailand, Vietnam: United Nations, 2012). Like Singapore, nations faced with durable below-replacement fertility may also attempt to counter population decline and aging through immigration, but this might prove politically challenging (Jones, 2012; National Population and Talent Division, 2012).

Fertility rates are expected to continue to decline in the five SEA nations still above replacement, albeit at the different paces noted above. By 2030–35, only Malaysia and the Philippines (due to a slow pace) and Timor-Leste (due to a late onset) are projected with fertility levels above replacement. These fertility projections are mere extrapolations of past trends, and reversal cannot be entirely ruled out. As noted in Indonesia, fertility seems to have stabilized and possibly increased slightly in the past 10 years, while the proportion of married women among 15–24 year olds increased slightly (United Nations, 2012) after a precipitous decline in the previous decades (Jones and Gubhaju, 2012). This inflection of these demographic trends might result from a reaction to secularization and globalization trends leading to an increase in religiosity (Hull, 2012).

The record from around the world seems to indicate that the completion of ongoing fertility transitions is all but certain, and that lulls and slight reversals are only temporary. A more speculative question is whether the region may experience the onset of a 'second' demographic transition, alongside the 'first' one still ongoing in some other parts of the region. As argued above, the fertility transitions of SEA have been driven by declining marital fertility rates, without necessarily involving major transitions in marriage, divorce, unmarried cohabitation, and childrearing or having children out of wedlock toward rates that have been associated with low fertility in Western nations.

To date, if by international standards, the proportions of women marrying are still relatively high across SEA nations, the trend away from universal and young marriages is clear. Surprisingly, the proportion ever marrying is lowest in Myanmar (85.2%, **Table 2**). Rather than a new trend, this might be linked to contemporary political uncertainties and to the traditionally accepted form of celibacy in order to look after aged parents (Jones and Gubhaju, 2012: 86). With smaller family sizes, older-parent care falls on an increasing proportion of the children's generation, and with economic restructuring, may now require work-related emigration and remittances from urban settings, increasingly conflicting with the traditional marriage process (Barbieri, 2009; Alipio, 2013). However, the clearer signs of decreasing proportions ever marrying are in Singapore (87.2%, **Table 2**), among ethnic Chinese communities in the rest of the region, and in some of the other large metropolitan areas (Jones, 2005). Given the current weight of the rural populations in most SEA nations still these changes are not too visible on national averages yet, but might soon become so with the likely continuation of rural-to-urban migration and possible diffusion to rural areas of new attitudes regarding marriage (Tey, 2007; Situmorang, 2007; Jayakody and Vu, 2009). Observed all over the world, the trend is not surprising and is

frequently associated with the expansion of educational and professional opportunities for women. While a major reason for marital postponement in SEA as well, rising educational levels are not the only factor as Jones and Gubhaju (2009) finds increasing proportions never marrying across all educational groups. A modest counterbalancing factor – visible, but still relatively small numerically – is the predicted increase in international marriages to males from countries confronted to the "marriage squeeze" generated by increasing male-to-female birth ratios (Jones and Shen, 2008; Yang and Lu, 2010).

Unmarried cohabitation seems to remain extremely rare in SEA, at least based on the standardized data that demographic surveys collect across many countries. In the region's national censuses, unmarried cohabitation only appears as a distinct marital status in the Philippines (Jones and Gubhaju, 2012). When unmarried couples openly live together, however, they are typically considered as married *de facto*. The census definition of marriage in Indonesia, which includes unmarried cohabitation (Hull, 2012), seems to reflect the general perception also prevailing in predominantly Buddhist nations. Elaborate and often expensive wedding ceremonies are socially desirable in the community, but Buddhism does not prescribe any particular ritual (Cherlin and Chamratrithirong, 1988). Unmarried cohabitation is likely more prevalent than data that suggest among the lower classes and in urban settings (Xenos and Kabamalan, 2007; Esara, 2012). Nonetheless, when married and unmarried partnerships are considered jointly, the prevalence of actual celibacy appears higher in SEA than in Europe (Jones, 2007).

In Western nations, increasing divorce rates are another feature of the second demographic transition (Lesthaeghe, 1983), consistent with the economic theory of marital instability (Becker et al., 1977). In SEA, however, some traditional societies were already accommodating high levels of marital disruptions (Jones, 1997; Hirschman and Teerawichitchainan, 2003). In Thailand, divorce rates were averaging about 15% after 20 years of marriage (Smith, 1981; Knodel et al., 1984), but were highest among Muslims, as also observed in Malaysia and Indonesia. Divorce there is relatively simple to obtain, at least for the husband, and was experienced by as many as 40% of men and women when arranged, early marriage was the norm (Jones, 1994), until the declining incidence of this marriage pattern brought a concomitant decline in divorce rates. In Cambodia, where marriage rates had remained relatively rare, however, the likelihood of divorce is now higher among couples who chose each other as marriage partners, and divorce rates have actually increased with the decline in arranged marriages (Heuveline and Poch, 2006). Slow increases in this 'modern' type of divorce are visible elsewhere in the region, including in populations where it was disapproved of before, such as those influenced by Confucian traditions (Jones and Gubhaju, 2012). Secular divorce still does not exist in the Philippines, where marriages can only be annulled by the Catholic Church.

Finally, out-of-wedlock birth ratios remain low, trivial even in some of the region's nations. As elsewhere in the LDR, there is evidence that premarital sexual intimacy is on the rise, in particular in the region's metropolitan areas (Brown et al., 2013; Ghuman et al., 2006; Gipson et al., 2012). A gradual change in extra-marital sexual behavior notwithstanding, there is little evidence to date to suggest that SEA will soon exhibit the high nonmarital fertility ratios of the United States or some North European nations. In these nations, out-of-wedlock fertility has maintained overall fertility fairly close to replacement level. In SEA, a more likely demographic path would seem to include the expectation of childbearing mostly within marriage, marital decisions still embedded in child–parent relationships, but increasingly the prerogative of individuals with changing aspirations, some of which may conflict with marriage and childbearing. In such a scenario, fewer and later marriages are typically paired with fertility substantially and durably below replacement (Jones, 2007).

Fertility Transition: Sub-Saharan Africa

David Shapiro, The Pennsylvania State University, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Fertility transition – the decline of fertility from high levels – emerged in the Third World following World War II. In sub-Saharan Africa the onset of fertility transition was delayed, and the pace of transition has also been distinctly slower than elsewhere in the developing world. Limited economic growth and development, low educational attainment, high infant and child mortality, and a strong cultural emphasis on the extended family all appear to have contributed to the delayed and slow fertility decline in the region. There is considerable diversity of experience with fertility decline among countries in the region, and stalling of fertility decline has been common.

Introduction

Fertility transition is part of the broader concept of the demographic transition, which describes the shift from the high rates of fertility and mortality that characterized most of human history to low rates of fertility and mortality that prevail in industrialized countries and increasingly in the developing world. The demographic transition unfolded during much of the nineteenth and early twentieth centuries in Europe, the United States, and elsewhere in what are now high-income countries. By contrast, it was not until after World War II that this transition emerged in the developing world (much of Asia, Africa, and Latin America).

Fertility Transition in the Developing World – a Comparative Perspective

Figure 1, based on the most recent United Nations estimates and projections, shows period total fertility rates and provides a comparative perspective on fertility transition in sub-Saharan Africa and other major regions in the developing world, dating back to 1950. The period total fertility rates (TFRs) indicate the number of children women would have during their lifetimes if they were to bear children at the rates prevailing in each particular period.

It is clear from the figure that fertility transition began to emerge in the Third World in the early decades of the second half of the twentieth century. Fertility declines are apparent for Latin America, Asia, and Northern Africa during the 1960s and 1970s. At the same time, sub-Saharan Africa stands out for the delay in initiation of fertility decline; overall decline is apparent only after 1980. In addition, following initiation of decline, the pace of that decline has been distinctly slower in sub-Saharan Africa than elsewhere.

As a consequence of both the later initiation and slower pace of decline, estimated current total fertility (for the period 2010–15) is substantially higher for sub-Saharan Africa as compared to the other regions. While Asia and Latin America and the Caribbean have estimated total fertility rates of 2.2 and the estimated rate for Northern Africa is 3, the corresponding figure for sub-Saharan Africa is 5.1. Hence, sub-Saharan Africa was the last major world region to initiate fertility decline, and its fertility remains substantially higher than fertility in the other major regions of the developing world.

Figure 1 Total fertility, by region, 1950–2050. Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat, World Population Prospects: The 2012 Revision, http//esa.un.org/unpd/wpp/index.htm.

Fertility Transition in Sub-Saharan Africa, by Region

Within sub-Saharan Africa, there is a notable difference in fertility between Southern Africa and the other sub-regions, as is evident from Figure 2 (also from United Nations data). Fertility estimates for Southern Africa (dominated by South Africa) look much like those for Asia and Latin America and the Caribbean, declining from early on in the post-World War II period and falling to well below three children per woman for the period from 2010 to 2015. However, the fertility rates for the other three sub-regions show delayed declines, beginning in the 1980s in Eastern and Western Africa and in the 1990s in Middle Africa. In addition, Middle Africa has had the highest estimated fertility for the past 25 years. For all three sub-regions there is sustained high fertility at present. For the period 2010–15, the estimated TFR for Middle Africa is 5.7, while for Western Africa, Eastern Africa, and Southern Africa the corresponding figures are 5.6, 4.9, and 2.5, respectively.

Fertility Transition in Sub-Saharan Africa, by Country

Further disaggregation, to the country level, shows substantial variation in fertility behavior. United Nations medium estimates of total fertility rates for individual countries for the period 2010–15 indicate that the total fertility rate is less than 4 in all five countries from Southern Africa, in Zimbabwe and Ghana, and in a few small island nations. These are the countries where fertility transition is most advanced. By contrast, half a dozen countries have estimated TFRs in excess of 6, including Niger (with an estimate in excess of 7.5), Mali, Somalia, Chad, Burundi, and Nigeria, the region's most populous country. In between, numerous countries are in various stages of fertility transition (Table 1).

In the literature on fertility transition, it is customary to consider the transition to have been initiated when the total fertility rate falls by at least 10% from some preexisting peak level. The United Nations Population Division reports estimates of the TFR for each country for 5-year periods beginning in 1950. There are 42 countries in sub-Saharan Africa with population of at least one million. Peak fertility in these countries typically is around seven children per woman, and varies from just under six in the Central African Republic, Gabon, and Lesotho to more than eight children per woman in Kenya and Rwanda.

In five of the 42 countries, estimated fertility in 2005–10 is greater than 90% of peak fertility. This is the case for Chad, Gambia, Mali, Niger, and Somalia. These, then, are the countries in which fertility transition has not yet begun. The (unweighted) average total fertility rate in these five countries is 6.8, and the range is from 5.8 (Gambia) to 7.6 (Niger). The average TFR constitutes 94% of the average peak fertility of 7.3 in these five pre-transitional countries.

There are 17 countries, distributed almost equally among Eastern, Middle, and Western Africa, which are in the early stages of fertility transition. Operationally, this group is defined here as consisting of countries in which the estimated fertility in 2005–10 represents more than 75 to 90% of the peak fertility. That is, in these countries the TFR has fallen by at least 10% from its peak, but not (quite) by as much as 25%. This is an arbitrary classification scheme, but it helps distinguish the countries in the region with respect to their position in the ongoing fertility transition in the region. The average total fertility rate in this group of countries is 5.7, and the range is from 4.9 (Central African Republic) to 6.5 (Angola and Burundi). The average TFR represents 82% of the average level of peak fertility.

Another dozen countries may be classified as mid-transitional. This group is operationalized here as countries in which the estimated TFR represents 60–75% of the peak fertility. Seven of these countries are in Western Africa and four others are in Eastern Africa. For this group, the average TFR is 4.9, with the range being from 4.2 (Ghana) to 5.3 (Ethiopia and Guinea-Bissau). Average peak fertility for this group is 7.2, so the average estimated fertility for 2005–10 represents 68% of the average peak fertility.

Finally, there are eight countries in which fertility has declined by more than 40% from its peak level. These are the countries in sub-Saharan Africa in which fertility transition is advanced. They include three countries from Eastern Africa, namely Kenya, Mauritius, and Zimbabwe, and all five countries

Figure 2 Total fertility, sub-Saharan Africa and its sub-regions, 1950–2050. Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat, World Population Prospects: The 2012 Revision, http://esa.un.org/unpd/wpp/indexhtm.

Table 1 Fertility in sub-Saharan Africa by stage of fertility transition: estimated fertility as of 2005–10 and peak fertility

Country	*Peak TFR*	*2005–10 TFR*	*Last/peak*
Pre-transitional			
Chad	7.41	6.85	92
Gambia	6.34	5.79	91
Mali	7.09	6.8	96
Niger	7.77	7.58	98
Somalia	7.7	7.1	92
Average	7.3	6.8	94
Early transition (last is 75+ to 90% of peak)			
Burundi	7.59	6.52	86
Malawi	7.6	5.83	77
Mozambique	6.6	5.57	84
South Sudan	6.92	5.43	78
Uganda	7.12	6.38	90
United Republic of Tanzania	6.8	5.58	82
Zambia	7.43	5.9	79
Angola	7.4	6.5	88
Cameroon	6.7	5.21	78
Central African Republic	5.95	4.85	82
Congo Republic	6.29	5.1	81
Democratic Republic of Congo	7.24	6.5	90
Benin	7.01	5.31	76
Burkina Faso	7.17	6.08	85
Guinea	6.63	5.39	81
Liberia	6.96	5.23	75.1
Nigeria	6.76	6.01	89
Average	7.0	5.7	82
Mid-transition (last is 60–75% of peak)			
Eritrea	6.97	5.2	74.6
Ethiopia	7.43	5.26	71
Madagascar	7.3	4.83	66
Rwanda	8.43	5.13	61
Gabon	5.72	4.29	75.00
Cote d'Ivoire	7.93	4.89	62
Ghana	6.95	4.22	61
Guinea-Bissau	7.41	5.28	71
Mauritania	6.79	4.96	73
Senegal	7.46	5.11	68
Sierra Leone	7.03	5.16	73
Togo	7.28	4.89	67
Average	7.2	4.9	68
Advanced transition (last is <60% of peak)			
Kenya	8.11	4.8	59
Mauritius	6.2	1.58	25
Zimbabwe	7.4	3.9	53
Botswana	6.7	2.9	43
Lesotho	5.86	3.37	58
Namibia	6.6	3.4	52
South Africa	6.3	2.55	40
Swaziland	6.87	3.75	55
Average	6.8	3.3	49

Note: First column shows the peak estimated TFR since 1950; second column gives the estimated TFR for the period 2005–10; and third column gives the latter as a percentage of the former.
Source: United Nations, Department of Economic and Social Affairs, Population Division, 2013. World Population Prospects: The 2012 Revision, CD-Rom Edition. New York. – data on estimated fertility from 1950 until 2010 for 42 countries with population in excess of one million.

in Southern Africa: Botswana, Lesotho, Namibia, South Africa, and Swaziland. The average total fertility rate in 2005–10 for this group of countries was 3.3. Mauritius and Kenya were the outliers, with TFRs of 1.6 and 4.8, respectively. The remaining countries had TFRs ranging from 2.55 (South Africa) to 3.9 (Zimbabwe). The average TFR of 3.3 for the group represents 49% of the peak estimated fertility.

From this detailed review of experience in individual countries, it is apparent that the vast majority of countries in sub-Saharan Africa have initiated fertility transition, although several countries have not done so and, using the criterion of a 10% decline from peak fertility, two other countries (the Democratic Republic of the Congo and Uganda) just barely qualify as having begun their fertility transitions. Among those countries in which fertility decline has been seen, there is clearly substantial variation in the pace of the observed declines, and Southern Africa stands out for more substantial declines. In the subsequent sections we address the question of which factors seem to be most relevant in influencing the pace of fertility decline. Before addressing that question and other more detailed aspects of the fertility transition in the region, it is useful to consider why sub-Saharan Africa was so slow to initiate fertility decline, as compared to other parts of the developing world.

Why Was Fertility Transition So Slow to Emerge in Sub-Saharan Africa?

The delay in initiation of fertility transition in sub-Saharan Africa was the subject of considerable speculation, particularly during the 1970 and 1980s (see, e.g., Lesthaeghe, 1989). Several different explanations were set forth, reflecting economic, social, and cultural factors. Before examination of these explanations, we consider a conceptual framework that is useful for examining fertility transition.

The Easterlin Framework for Fertility Analysis

Demographic transition, as it unfolded in Europe, the United States, and elsewhere, was broadly associated with economic growth and development. Early work by Gary Becker (1960) and by Becker and Lewis (1973) emphasized that economic development was likely to contribute to decreased demand for numbers of children, and greater expenditures on education and health per child, characterized as higher quality of children. Richard Easterlin (1975; Easterlin and Crimmins, 1985) elaborated an economic approach to fertility that incorporated Becker's approach focused on demand for children and added elements pertaining to supply of children and costs of fertility regulation.

In brief, the Easterlin model emphasizes three broad categories through which the basic determinants of fertility operate and which influence, in turn, the proximate determinants of fertility. These three categories are the demand for children (the number of surviving children parents would want if fertility regulation were costless); the supply of children (the number of surviving children parents would have if they did not deliberately limit fertility); and the costs (subjective and objective) of fertility regulation.

Following Becker, a couple's demand for children is treated as analogous to the demand for goods and services. In particular, demand depends on household income, on the

cost (price) of children, and on parents' tastes or preferences for children relative to other goods and services that provide satisfaction (utility) to the couple. Other things being equal, higher income is expected to be associated with a greater demand for children (i.e., children are assumed to be a normal good). However, greater demand for children may be realized at least in part by greater resource endowments per child rather than simply by an increase in the number of children. In this respect, the demand for children or child services may be seen as comparable to the demand for consumer durable goods more generally, where higher income often translates into increased demand for quality rather than simply increased quantity.

Greater resource endowments (i.e., higher expenditures) per child are typically described in the economics literature on fertility as expenditures for child quality, and there is considerable discussion in the literature of quality–quantity tradeoffs. In empirical work, the two areas most commonly studied where resources are expended to enhance child quality are education and health.

The greater the cost of children, the lower is the quantity demanded. The cost of children includes not simply the direct costs of goods and services that are complementary to children, but also the indirect or opportunity cost of the mother's time spent in child care (often measured using estimates of the woman's earning power, or potential wage rate, in the labor market). Indeed, for children of given quality, it is typically differences among women in the opportunity cost of time that result in differences across households in the cost of children.

The stronger are a couple's (relative) preferences for children, the greater the demand for children, other things being equal. In considering this aspect of the demand for children, it is necessary to take into consideration the tastes relating to child quality. More generally, economics does not have a lot to say about tastes, but presumably this factor may be related to cultural factors such as ethnicity or religion, and it may also be related to individual factors such as educational attainment (e.g., greater mother's education has been found to be related to stronger preferences for greater child's education).

The supply of children reflects two factors: a couple's natural fertility and the chances of child survival. Natural fertility refers to the number of births a couple would have if they took no action aimed at limiting fertility behavior (i.e., in societies in which deliberate fertility control is not practiced). Cultural differences in behaviors that influence the likelihood of a birth (e.g., in duration of breast feeding or in the observance of periods of postpartum abstinence) can lead to differences in natural fertility between different natural fertility populations. Since the potential supply of children in the Easterlin framework refers to the number of children surviving to adulthood, it is clear that supply also varies inversely with the level of mortality. Hence, reductions in mortality increase the supply of children.

The costs of fertility regulation incorporate a couple's attitudes toward and access to fertility control methods and supplies. There are two types of costs of fertility regulation: psychic costs and market costs. Psychic costs refer to the displeasure associated with the practice or idea of fertility control, while market costs are the money and time costs necessary to learn about and use specific contraceptive techniques.

Couples have a motivation for fertility regulation if the potential supply exceeds the quantity of children demanded. This does not necessarily translate into efforts to control fertility – that depends also on the costs of fertility regulation. Given the extent of the motivation to limit fertility, the lower the costs of fertility regulation the more likely a couple is to opt for contraception. In this framework, then, family planning programs can lead to fertility reduction via reducing both the market costs and the psychic costs of contraception.

The basic determinants of fertility behavior include underlying socioeconomic conditions, or what Easterlin and Crimmins describe as modernization variables such as education, urbanization, and modern sector employment, as well as cultural factors such as ethnicity and religion, and other determinants such as genetic factors. These basic determinants influence fertility through their impact on the demand for children, the supply of children, and/or the costs of fertility regulation.

Between the basic determinants of fertility and realized fertility behavior are the proximate determinants of fertility. That is, the basic determinants influence fertility only indirectly, through their influence on the proximate determinants. It is these proximate determinants which are seen as determining fertility directly. Following Davis and Blake (1956) and Bongaarts (1978), the proximate determinants include factors such as extent of exposure to intercourse (heavily influenced by age at marriage, but note that cultural practices regarding intercourse outside of marriage will also be relevant here), fecundability (including frequency of intercourse), duration of postpartum infecundability (related especially to breast feeding durations, an important factor keeping fertility in sub-Saharan Africa below its biological maximum), sterility, and the use of deliberate fertility control including contraception and induced abortion.

From the perspective of this conceptual framework, the onset of fertility transition is likely to reflect declining demand for numbers of children along with increasing supply, eventually resulting in excess supply and hence a motivation for fertility control. As fertility regulation is adopted, fertility begins to decline. Consider now the explanations offered for the delayed emergence of fertility transition in sub-Saharan Africa.

Economic Development and Fertility

With respect to the association between economic development and fertility, it was apparent from historical evidence that while there was no indication that a specific level of development or industrialization would trigger the onset of fertility transition, in the wake of economic growth and development fertility decline would typically occur. This was evident in the developing world as well (Bryant, 2007). From this perspective, then, it was argued that sub-Saharan Africa's comparatively slow economic advancement was delaying the onset of fertility decline.

The region has remained predominantly agricultural throughout the years: as of 2010, it is estimated that more than 60% of employment in the region is in agriculture, higher than

anywhere else in the developing world. Becker's early work on fertility (1960) emphasized the importance of the net cost of children as an influence on the demand for children. To the extent that children in rural areas are able to contribute to agricultural production – as is typically the case in the land-abundant, low-technology slash-and-burn agriculture that typifies much of the region – this will lower their net cost and hence, other things being equal, be associated with greater numbers of children demanded and hence higher fertility.

Education, Infant and Child Mortality, and Fertility Transition

In addition to the direct economic influences on fertility, there are socioeconomic factors that contribute to high fertility in the region. Most notable in this regard are the comparatively low level of education among women in much of the region (Shapiro, 2012), and the relatively high level of infant and child mortality. Women's education and fertility are inversely related, for a variety of reasons. Women with more education typically desire more education for their children, reflecting a quality–quantity trade-off with respect to fertility, resulting in lower numbers of children demanded. Such women are also more likely than their lesser-educated counterparts to have some say in couples' decisions about childbearing. Better-educated women are also more likely to use contraception and to use more effective contraceptive methods than their lesser-educated counterparts. Hence, the low levels of education of women in sub-Saharan Africa, with some countries having high proportions of women with no schooling, tended to inhibit fertility decline.

High rates of infant and child mortality also helped perpetuate high fertility. Current United Nations estimates of mortality for sub-Saharan Africa, Asia, and Latin America show that infant mortality rates are highest by far for sub-Saharan Africa, being more than twice as high as those in Asia and nearly four times as high as in Latin America. Under-five mortality is almost three times higher in sub-Saharan Africa than in Asia and nearly five times higher than in Latin America. In the Easterlin framework for fertility analysis, infant and child mortality serve as a check on the supply of children. Hence, the likelihood of excess supply and hence a motivation for fertility control is low. With adult children serving as the primary means of old-age support for parents, high infant and child mortality translate into high demand for numbers of births, to assure adequate old-age support.

Cultural Factors and Fertility Transition

In addition to these socioeconomic factors, there were a number of cultural factors unique to sub-Saharan Africa that promoted or facilitated ongoing high fertility (cf Lesthaeghe, 1989; Romaniuk, 2011). Probably the most important in this regard was the emphasis on the extended family and the lineage. Children were viewed not simply as the offspring of their biological parents, but also as reinforcing the strength of the extended family and the clan. Hence, the birth of a child was not simply a matter for the parents, but because it expanded the lineage, it was a concern for the larger web of relations as well. Further, the widespread practice of child fostering within the extended family, by providing opportunities to foster out children, served to reduce the costs of children to their parents and thus contributed to high demand for numbers of children.

Another cultural aspect particularly relevant in sub-Saharan Africa is polygyny. While over time the incidence of polygyny has declined, it remains prevalent in a number of countries. Romaniuk (2011: p. 9), while noting that polygynous women often have lower fertility than monogamous women, points out that this is largely a selection effect, and argues that polygyny contributes to "a more complete mobilization of women into marriage and reproduction."

Onset, Current State, and Specificities of Fertility Transition in Sub-Saharan Africa

The World Fertility Survey, carried out during the 1970s and early 1980s in 42 countries, including 11 in sub-Saharan Africa, confirmed that at the level of national populations the region had still not experienced the onset of fertility transition. However, by the early 1990s, surveys carried out in the late 1980s as part of the Demographic and Health Surveys (DHS) program funded by the United States Agency for International Development provided clear evidence of declining fertility. Botswana, Ghana, Kenya, and Zimbabwe were the first countries to show this evidence, and during the 1990s additional DHSs provided indications of fertility transition in numerous other countries, albeit at different paces. As noted earlier, there remains a small group of countries in which fertility transition has not yet been initiated.

Fertility Transition and Economic Conditions

While experience elsewhere in both the industrialized world and the developing world suggests that economic growth and development will ultimately encourage fertility decline, there is also literature suggesting that economic adversity may contribute to initiation of fertility transition. This notion of crisis-led transition was discussed early on by Lesthaeghe (1989), and a study by the National Research Council (1993) found evidence of economic adversity contributing to lower fertility, primarily via delays in initiation of marriage and first births. Country-specific studies, such as that by Eloundou-Enyegue et al. (2000) for Cameroon, also found evidence that economic adversity could contribute to the onset of fertility transition.

Onset of Fertility Transition by Place of Residence

While the onset of fertility decline at the national level was not apparent prior to the end of the 1980s, subsequent work has made it clear that fertility transition in sub-Saharan Africa had begun in a number of urban places well before then (Garenne and Joseph, 2002; Garenne, 2008). This initiation of transition in urban areas was similar to the fertility transitions that had taken place earlier in Asia and Latin America. Shapiro and Tambashe (2002), in assessing fertility transition in the region, suggested a three-phase transition: initially, fertility

began to decline in urban places while remaining stable in rural areas; subsequently, fertility declined in both urban and rural places, but more rapidly in urban areas; and finally (with fertility having reached comparatively low levels in urban places) fertility decline in rural areas outpaced that in urban places. They also noted that for the most part, urban fertility transition was especially pronounced in the large capital cities.

The differences by place of residence in the timing of the onset of fertility transition are consistent with theoretical emphasis on the net costs of children: both children's prospective contribution to agricultural production in rural areas (noted above) and the higher cost of living in urban places make the net cost of children higher in urban settings. In addition, since infant and child mortality rates are typically greater in rural areas, this means that the supply of children in the Easterlin framework for fertility analysis (defined as the number of births surviving to adulthood) is greater in urban areas, and this in turn increases the likelihood of excess fertility and hence a demand for fertility control in urban places.

The especially low fertility that is often apparent in capital cities also appears in some cases to reflect the effects of economic adversity. Antoine (2006), in a study of four capital cities in the region, found evidence that economic adversity had contributed to slowing of rates of entry into marital unions and consequently to lower levels of fertility. Gurmu and Mace (2008) reported similar findings for Addis Ababa in Ethiopia.

Stalling of Fertility Transitions and Factors Influencing the Pace of Fertility Decline

Various countries in sub-Saharan Africa are at different stages of fertility transition, as noted above. In addition, as Bongaarts (2008), Shapiro and Gebreselassie (2008), and others have emphasized, stalling of fertility transition – i.e., a halt in the decline of fertility for some period of time – has been observed in a number of countries in the region. Observations of stalling have most commonly been made using data from the DHSs, since multiple surveys for the same country allow for a direct examination of stalling.

For example, there are 27 countries in sub-Saharan Africa that have had multiple DHSs. Three of these countries have not yet begun fertility transition. But of the remaining 24 countries, just over half have reported a TFR in one survey that was not lower than the TFR reported in the previous survey. This simple measure of stalling is but one of multiple possible measures. Of the 13 countries with stalls in the reported TFRs, five subsequently showed a resumption of fertility decline. At present, with eight countries in a situation of fertility stall, the phenomenon of stalling appears to be more common than was the case earlier in the African fertility transition.

Bongaarts (2008) has suggested that the slower pace of socioeconomic progress in sub-Saharan Africa as compared to elsewhere in the developing world may be pertinent in accounting for the slower pace of fertility decline in the region and the presence of stalling of fertility transitions. Shapiro and Gebreselassie (2008) and Shapiro (2012) have analyzed data from successive pairs of DHSs carried out in sub-Saharan Africa, examining the relationships between the magnitudes of fertility decline between surveys and changes in various factors that are presumed to influence the pace of fertility decline. Those studies have found that women's educational attainment and infant and child mortality are the key factors that appear to be related to the pace of fertility decline within the region. Over all, the longer-term trends show increases in women's educational attainment and declines in infant and child mortality occurring as fertility tends to decline. Multivariate regression analyses of data from DHSs, at national, urban–rural, and regional levels within countries, show that more rapid increases in women's education are associated with faster declines in fertility, and that more rapid declines in infant and child mortality are also associated with faster declines in fertility.

The use of modern contraception was a major factor in contributing to fertility transition elsewhere in the developing world. However, it appears that the relationship between contraceptive use and fertility is weaker in sub-Saharan Africa than elsewhere (Westoff and Bankole, 2001), and the analyses referred to in the preceding paragraph found only limited evidence of increased contraceptive use as a factor influencing the pace of fertility decline. One factor that may be relevant here is recourse to abortion. While there are difficulties gathering information on abortion (such information is not available in the DHSs, for example), there are a number of studies that suggest that recourse to abortion, particularly among younger women, is not uncommon in many places in the region, and especially larger urban places. Rossier (2010), in one such study, suggested that in the early stages of fertility transition, there is likely to be growing recourse to abortion as a means of limiting fertility, but that as transition proceeds, there will be greater reliance on modern contraception to control fertility, and a corresponding reduction in the incidence of abortion.

Is the African Fertility Transition Different from the Transitions Elsewhere?

A question of some interest is whether fertility transition in sub-Saharan Africa is qualitatively different from the earlier fertility transitions in Asia and Latin America (as opposed to simply unfolding more slowly). This issue was first raised by Caldwell et al. (1992), who suggested that fertility transition in sub-Saharan Africa would be characterized by similar declines across all age groups, in contrast to the earlier transitions in which fertility declines were initially concentrated among older women. A recent paper by Bongaarts and Casterline (2013) failed to find evidence of similar declines in fertility across age groups. However, comparing the current transition in sub-Saharan Africa with the earlier transitions elsewhere when they were at a comparable overall level of fertility, Bongaarts and Casterline did find some clear differences. Ideal family size is distinctly higher in sub-Saharan Africa than it was in Asia and Latin America when those regions were at a similar stage of the transition as reflected in the overall total fertility rate. Bongaarts and Casterline argue that this comparatively high ideal family size contributes to the slower pace of fertility transition in the region as compared to elsewhere in the developing world. Africa also is characterized by longer birth intervals.

Moultrie et al. (2012) have also addressed the question of whether fertility transition in sub-Saharan Africa is different

from earlier transitions. They focus on postponement of fertility and the corresponding birth intervals, using data from numerous DHSs from two dozen countries in the region. Their analyses indicate that there has been a lengthening of birth intervals for each country in the region that they analyze, but that the lengthening of these intervals does not show systematic variation either by woman's age or parity. Noting that this appears to differ from earlier fertility transitions elsewhere, they argue that "the fact that, across the 24 countries studied, median birth intervals have lengthened largely independently of either age or parity provides empirical support for our contention that the African fertility transition is distinctively different" (Moultrie et al., 2012: p. 251).

Future Prospects

The United Nations Population Division projects that by the middle of this century, the TFR for sub-Saharan Africa will have fallen from its current level of 5.1 to a level of 3.2 (Asia and Latin America are projected to have fertility below 2 by mid-century). sub-Saharan Africa is already the most rapidly growing region of the world, and United Nations projections anticipate that the region's population will more than double between 2015 and 2050, to exceed two billion people. The region's share of world population is projected to increase from about 13 to almost 22%. At the same time, however, the prevalence of stalling of fertility transition in the region calls into question these projections.

Whether this projected continuation of fertility decline will be realized will clearly depend on future socioeconomic development in the region. If the longer-term trends toward increasing educational attainment and declining infant and child mortality continue, prospects for ongoing fertility transition will be enhanced. Shapiro (2012) found that increased schooling of women to and beyond the secondary level appeared to be associated with an acceleration of the pace of fertility decline; hence, increased educational attainment of women may lead to a faster pace of fertility transition in the coming decades.

Likewise, economic improvement that would enhance the payoffs to investments in children's schooling and health would also be expected to contribute to ongoing fertility transition. This would come about via increased incentives to invest in child quality, which would likely result in declines in ideal family size and hence reduced demand for number of children. But given the weak state of many economies in the region, it is not at all clear whether such improvement will be realized.

Fertility Trends in the Formerly Socialist Countries of Europe

This article is a revision of the previous edition article by A. Avdeev, volume 8, pp. 5602–5605, © 2001, Elsevier Ltd.

Abstract

The formerly socialist countries of Europe have experienced a remarkable demographic transformation since the fall of the Berlin Wall in 1989. On many dimensions of fertility and family formation, much of the region now looks like Western Europe: below-replacement fertility rates, rising age at first marriage and first birth, and high and increasing nonmarital births characterize many countries formerly distinguished by replacement-level fertility and early, near-universal marriage and childbearing. Some of these changes appear to be driven by increased opportunities and rising returns to education for women, but much research on these issues remains to be done.

Under socialism, most countries of Eastern Europe and the former Soviet Union exhibited a distinctive pattern of fertility and family formation: marriage and first birth occurred at relatively young ages; births occurred predominantly within registered marriages; total fertility rates were at or near the replacement level of fertility (approximately 2.1 children per woman); and abortion rates were much higher than in other developed countries. After the collapse of socialism in 1989–91, these features of the demographic landscape in the region changed rapidly and profoundly. Across virtually all formerly socialist countries of Europe, fertility rates declined sharply in the 1990s and remain well below replacement levels. First births occur at significantly older ages and are much more likely to be registered as nonmarital births. Abortion rates have declined notably as well. In all dimensions of fertility, the formerly socialist countries of Europe appear to have converged with those of Western Europe and fertility patterns are now similar across almost all European countries, both East and West.

For the purposes of this article, the 'formerly socialist countries of Europe' refers to Albania, Bulgaria, the Czech Republic, Hungary, Poland, Romania, the Slovak Republic, the countries of the former Yugoslavia (Bosnia and Herzegovina, Croatia, Kosovo, Macedonia, Montenegro, Serbia and Slovenia; however demographic data are lacking for many of these successor states), as well as the former Soviet republics of Belarus, Estonia, Latvia, Lithuania, Moldova, Russia and Ukraine. The fertility data in this article are from the most recent national statistical or demographic yearbooks published by each country. When such data are missing, data from Eurostat (http://epp.eurostat.ec.europa.eu/portal/page/portal/statistics/search_database) or Demoscope (http://demoscope.ru/weekly/pril.php) are used.

Fertility Trends under Socialism: A Distinctive Pattern

Fertility Trends 1945–89

Like most countries in Western Europe, the countries of Eastern Europe and the Soviet Union began their fertility transitions in the early twentieth century and recorded sustained fertility declines for several decades prior to World War II. In Russia, for example, it is estimated that the total fertility rate fell from 6.7 children per woman in 1927 to 4.3 children per woman in 1940, only 13 years later (Andreev et al., 1998). (The total fertility rate is calculated based on current age-specific birth rates (ASBRs) and represents the average number of children a woman can be expected to have during her lifetime.) In the early postwar period, however, fertility trends began to diverge markedly between East and West: Western Europe experienced a mild postwar baby boom, while fertility continued to decline across the socialist countries. By the mid-1960s, the total fertility rate had fallen below the replacement level of fertility in many socialist countries, including Hungary, the Czech Republic, Romania, and the Soviet republics of Russia, Ukraine, Estonia, and Latvia. Some analysts attribute this decline in fertility to the wave of abortion liberalization that occurred across the region in this period, beginning with the re-legalization of abortion in the Soviet Union in 1955 (David, 1982). Possibly in response to pronatalist measures undertaken in many countries in the 1970s, the total fertility rate stabilized in Eastern Europe and the western Soviet republics at around 2.0–2.5 and remained at this level until the mid-1980s (see **Figure 1**) (The sharp increase in the total fertility rate in Romania in 1967 was due to the imposition of Decree 770 in late 1966, which replaced Romania's liberal abortion policy with severe restrictions on the availability of abortion. See David (1999) for further details on abortion policy in Eastern Europe and the Soviet Union and its successor states.). In contrast, total fertility rates declined in Western Europe during this period, and as a result the socialist countries emerged as the highest fertility region in Europe by 1980.

The Socialist Fertility Pattern

The transformation of patterns of fertility and family formation that began in Western Europe in the 1970s and 1980s virtually bypassed Eastern Europe and the Soviet Union in these years. The transformation in Western Europe was marked by rising age at first marriage and at first birth, rising out of wedlock birth rates, and total fertility rates below the replacement level in many countries. In the socialist countries, in contrast, age at first birth remained stable or trended downward in the 1970s and 1980s (**Figure 2**). As an example of this divergence of fertility patterns, the mean age at first birth fell from 24.1 to 22.8 in Estonia between 1970 and 1989, while it increased in France from 23.9 to 25.9 in the same years.

Marriage and first birth both took place at relatively young ages in Eastern Europe and the Soviet Union, with women

Figure 1 Total fertility rate, 1960–2011.

entering marriage at an average age of 21–22 years, soon followed by first birth at an average age of 22–23 years in most countries. Any subsequent births were closely spaced, so that most women completed their childbearing at relatively young ages. By far the highest rates of childbearing occurred among women aged 20–24. In Western Europe, marriage and fertility postponement increasingly became the norm, leading to rising age at first birth and the highest fertility rates occurring among women aged 25–29. Marriage and childbearing were near-universal in the socialist countries; the rate of childlessness was near the biological limit of 5–10%, well below the rates of childlessness in West European countries (Sobotka, 2011). As is well known, abortion rates were high in the socialist countries, with abortion being used as the primary means of birth control due to limited alternative contraceptive options. The highest abortion rates occurred in the western republics of the Soviet Union (Russia, Ukraine, Belarus) and in Romania prior to 1967; for instance in 1980 the number of abortions per 100 births in Russia was 205. In the United States in the same year, the ratio was 43 abortions per 100 births.

Influence of the Socialist System on Fertility Patterns

This 'East European reproductive pattern' – distinguished by young age at first marriage and first birth, stable fertility rates near the replacement level of fertility, and high abortion rates – likely reflects the incentives created by the institutional features of the socialist system as implemented in Eastern Europe and the Soviet Union, as well as the pronatalist policies pursued by many socialist governments in the 1970s and 1980s. The features of the socialist labor market that likely influenced fertility choices include the high job security and low unemployment rates, as well as the compressed wage differentials and relatively low rates of return to higher education that characterized the wage structure in most countries. In these circumstances, women had little economic incentive to delay

Figure 2 Age at first birth, selected countries, 1970–2011.

marriage and childbearing in order to invest in education: due to the relatively low payoff to additional years of education and the limited opportunities for career advancement (particularly for women), the opportunity cost of early childbearing was relatively low. Housing shortages in many countries added to the incentive to marry and have a child at a relatively young age, as priority in the allocation of apartments was given to married couples with children (Sobotka, 2011). Without a means to advance in the housing allocation, children often continued to live with their parents well into adulthood, often for years after marriage.

In addition to the priority in housing allocation given to families with children, many countries of Eastern Europe and the Soviet Union adopted explicitly pronatalist policies in order to promote higher birth rates. These policies included generous maternal leave policies, birth payments, child benefits, and the widespread provision of free- or low-cost child care; most of these policies were targeted toward increasing second- and third-order births. The effectiveness of these policies in increasing completed fertility has been widely debated by demographers and policymakers, and most analysts argue that the pronatalist policies of the socialist countries only temporarily increased birth rates while having a modest (if any) impact on completed fertility (David, 1982; Sobotka, 2011; Frejka and Zakharov, 2012).

Fertility in Postsocialist Countries: Convergence of East and West

The socialist system collapsed in Eastern Europe beginning in 1989, soon followed by the dissolution of the Soviet Union into its 15 successor states in 1991. Most countries subsequently embarked on an arduous process of transition to market economies, a process unevenly implemented across the region and resulting in mixed outcomes, from the rapid and more successful reformers (Poland, Czech Republic, Hungary) to the more gradual and less successful reformers (Belarus, Ukraine). Despite the diversity of reform experiences, however, the sweeping demographic changes that have occurred since 1990 have been remarkably consistent across almost all formerly socialist countries, resulting in a new pattern of fertility and family formation that is highly similar to that of Western Europe.

Declining Total Fertility Rates

In the immediate aftermath of the fall of communism in the early 1990s, fertility rates in the formerly socialist countries of Europe plummeted to often unprecedented levels. The lowest levels were recorded in Bulgaria, with a total fertility rate of 1.09 in 1997, and in Ukraine, with a total fertility rate of 1.085 in 2001. These appear to be the lowest fertility rates ever recorded in a European country during peacetime. The fertility decline occurred in all countries of the region and was similar in magnitude, with the average total fertility rate falling from about 2.0–1.4 in all countries despite the wide variety of transition strategies and varying degrees of success in restoring the macroeconomies to positive economic growth. For example, the decline of the total fertility rate in Belarus, one of the most gradual reformers, is nearly identical to the decline of the total fertility rate in the Czech Republic, one of the most rapid and successful reformers (see Figure 1). The fertility decline reached its nadir in 1999–2000, then reversed slightly after 2000, but fell back again in 2009–11 following the 2008 financial crisis. In all countries the total fertility rate remains well below the replacement level of fertility. The number of births in the region is now so low that in many countries the rate of natural increase of the population (births minus deaths) is negative, implying a declining population size in the absence of substantial in-migration. Negative natural increase occurred in 2011 in Belarus, Bosnia and Herzegovina, Bulgaria, Croatia, Estonia, Hungary, Latvia, Lithuania, Romania, Russia, Serbia, and Ukraine. Only in Russia immigration was large enough to offset the negative natural increase so that positive population growth was recorded in that year; all of these other countries registered negative population growth in that year.

Postponement or Permanent Decline?

A key question is whether this fertility decline represents a permanent transition to below-replacement fertility levels or a temporary decline driven by women deciding to delay rather than forego childbearing. As demographers have noted, it is difficult to separate the 'tempo' effect of a change in fertility timing from the 'quantum' effect of a change in completed fertility, and this is especially true during periods of rapidly decreasing fertility rates: when fertility rates are declining quickly, fertility indicators such as the total fertility rate can be highly inaccurate indicators of completed cohort fertility. In particular, when the decline in fertility is due to postponement of childbearing, the total fertility rate is biased downward (Billari, 2008).

There are indications that at least some of the decrease in fertility represents a postponement effect rather than a 'quantum' effect; the dramatic increase in age at first birth across countries, as illustrated in Figure 2, is perhaps the strongest evidence of this. For example, the average age at first birth in Hungary increased from 22.99 in 1990 to 28.23 in 2010, an increase of 5.24 years in just 20 years. In the Czech Republic, the average age at first birth increased by 5.1 years over the same period, from 22.5 to 27.6 years. This increase in age at first childbearing is astonishingly rapid and occurred in roughly half the time it took for a similar increase in West European countries. In Norway, for example, the average age at first childbearing increased steadily from 1970 to 2010, from 23.2 to 28.2 – an increase of 5.0 years over a 40-year period. As of 2011, the average age at first birth in many East European countries had nearly converged with West European levels of about 28–29 years.

The postponement of childbearing is also illustrated by the changes in ASBRs in these countries. As previously noted, across all of the formerly socialist countries of Europe, by far the highest birth rates occurred among women aged 20–24; this pattern was remarkably stable for several decades prior to 1989. Due to the postponement of fertility, however, in nearly all post-socialist countries women in the 25–29 age group now have the highest birth rates. The trends in ASBRs are illustrated in Figure 3 for two representative countries, Russia and Hungary. Russia's ASBR pattern is characteristic of many

Figure 3 Age-specific birth rates, 1975–2011.

countries of the former Soviet Union, such as Ukraine and Belarus, while Hungary's pattern is typical of many Central European countries. Both figures illustrate that, until the 1990s, women aged 20–24 had the highest birth rates in both countries, followed by women aged 25–29. The decline in fertility rates in the 1990s was especially steep for women aged 20–24 in both countries as well as across the region overall. In Hungary birth rates have increased among all women aged 30 to 44, and as of 2010 the birth rate of 30- to 34-year-olds actually exceeded that of 25- to 29-year-olds. This 'crossing' of the 30–34 ASBR over that of the 25–29 ASBR also occurred in the Czech Republic in 2011. This 'crossing' has also occurred in many West European countries, beginning with Spain (1995) and Italy (1997), followed by Switzerland (2001), Sweden (2002), United Kingdom (2004), Greece and Portugal (2005), Germany and Finland (2006), and Norway (2010). In all of these countries, women in the 30- to 34-year-old age group continue to have the highest birth rates of all women age 15–49. Later childbearing is also occurring in Russia, with women aged 25–29 now having the highest birth rates as well as higher birth rates among women age 30–44. These changes in ASBRs and age at first birth represent fundamental shifts in the long-established patterns of the age structure of fertility, indicating that the region is becoming much like Western Europe in which the majority of childbearing is postponed until the early thirties.

Despite the evidence of fertility postponement, it is likely that the fertility decline in formerly socialist countries also reflects a reduction in completed cohort fertility. The extent of this change will not be known with certainty until the cohorts of women of childbearing age in the 1990s have reached the end of their childbearing years, but some early evidence is suggestive of a real decline in completed fertility. Results of the 2010 population census of Russia, for example, indicate that women born in 1946–55, whose reproductive years were largely completed prior to the transition, had an average of 1.85 live births in their lifetime. Women born in 1966–70, whose reproductive years coincided with the most turbulent period of transition in the 1990s, had an average of 1.64 live births, and women born in 1971–75 had 1.51 live births (fertility is not complete for this latter group) (Goskomstat of Russia, 2012).

Causes of the Fertility Decline?

Assuming that the fertility decline is at least in part real, rather than due to postponement, a number of possible explanations for the decline of fertility across the formerly socialist countries of Europe have been offered by observers. These include the loss of income associated with the collapse of GDP in the 1990s, the increased economic uncertainty caused by the transition from socialism to capitalism, and the decrease in the number of state-supported nurseries and preschool facilities as well as the near-disappearance of day care facilities provided by enterprises. In addition, increased returns to education have strengthened the incentive for young adults to obtain higher education, leading to the postponement of marriage and first births for many women. Analysts also argue that the new economic and political freedoms that accompanied the collapse of the socialist system created new opportunities for individual fulfillment, opportunities previously unavailable under socialism, which in turn raises the opportunity cost of childbearing and may further reduce fertility (Sobotka, 2011). However, credible evidence identifying the causes of the fertility decline in the transition economies is limited, so much of this discussion is speculative.

Other Fertility Trends

Other demographic changes across the region occurred with similar swiftness and further underscore the convergence of the Eastern pattern of fertility and family formation with that of West European countries. In particular, nonmarital birth rates have increased significantly in most of the formerly socialist countries, and have even surpassed the nonmarital birth rates of some West European countries. As shown in **Figure 4**, the share of births occurring outside of marriage increased in the region beginning in the late 1980s and early 1990s and has accelerated since those years. The highest nonmarital birth proportion occurs in Estonia, with 60% of all births occurring outside of registered marriage, followed closely by both Slovenia and Bulgaria. West European countries with high nonmarital birth shares include France (55.8% of births in 2011), Norway (55.0%), and Sweden (54.3%). Marriage rates have also fallen across the region while divorce rates have increased (see

Figure 4 Nonmarital births, 1960–2011.

Heleniak, 2010; Brainerd, 2012, for more detailed discussions of demographic trends in formerly socialist countries).

Figure 5 illustrates that the decline in birth rates was not achieved through increasing abortion rates. On the contrary, abortion rates have plummeted in most countries in the decades since 1989. For instance, in 1989 the number of abortions per 100 births in Belarus was 167, but by 2010 this ratio had fallen to just under 31. This level is similar in magnitude to that of the United Kingdom (29 abortions per 100 births in 2009) and the United States (23 abortions per 100 births in 2009). While abortion rates remain high in a number of postsocialist countries (Russia, Estonia, Bulgaria, Hungary, Romania) compared with other Western countries, the decrease in abortion rates is substantial in all countries and appears to be due at least in part to the increased availability of modern contraceptive methods in the 1990s and a resulting substitution of contraception for abortion. (The decline of abortion in Poland is due to stringent restrictions imposed on abortion in that country in the early 1990s.)

Concluding Remarks

The demographic transformation of the formerly socialist countries of Europe has been remarkable in its speed and scope. Many East European countries now resemble West European countries in their patterns of later marriage and childbearing, rising nonmarital births, and below-replacement fertility rates. These changes in fertility and family formation will likely have far-reaching consequences for each country's population size and age structure, as well as for the well-being of children in the region. The changes in fertility patterns in postsocialist countries also demonstrate the remarkable degree to which major individual life choices – when to marry, when to have a child, and how many children to have – are influenced by the broader social and economic circumstances in which we live, and how rapidly these choices can shift under circumstances of profound societal change. As has long been the case even before the fall of communism, the unique demography of Eastern Europe

Figure 5 Abortions per 100 births, 1989 and 2010.

and the former Soviet Union presents a myriad of questions for researchers to investigate.

Fetishism

Abstract

The concepts of 'fetish' and 'fetishism' (the adoration of objects and natural events) are some of the most controversial and contradictory in the history of anthropology and Western thought in general. In this article, we will present a brief history of these terms, from their origins in the encounters between West Africans and European traders in the seventeenth and eighteenth centuries, to current anthropological discussions on the nature–culture divide and the agency of things.

'Fetishism' could be defined, in very wide terms, as the adoration of objects and natural events. The 'fetish' would be this very object of adoration: not just the representation or image of a divinity, but also a material object or natural event that is worshiped as a divinity itself. These terms originally make reference to religious worship, but they have also been applied to other domains in which things acquire the qualities of persons – like in Marxist commodity fetishism or Freudian sexual fetishism.

Fetish and fetishism are two of the most controversial and contradictory terms in the social sciences. They have been explicitly rejected as anthropological concepts since the late nineteenth century; for Marcel Mauss, they revealed an 'enormous misunderstanding' (Iacono, 1992: 116). And yet, in recent decades, there has been a growing interest in this very misunderstanding, what William Pietz called "the problem of the fetish" (Pietz, 1985, 1987, 1988). The 'problem' of the fetish touches upon some of the basic distinctions of Western thought: people and things, action and event, subject and object, culture and nature, religion and economy. The questioning of these very distinctions in recent anthropology has inevitably brought the problem of the fetish back to the center of attention.

Origins of the Term

To address the 'problem of the fetish,' we should start by the original 'misunderstanding' that generated it. As Pietz says (1985: 5), the 'fetish' is a cross-cultural and radically historical event: it was born in the writings of European travelers to West Africa in the seventeenth century, to identify a supposedly African phenomenon. The *Encyclopédie Française* of Diderot and D'Alembert defined *fétiche* in the following terms: "Name that the peoples of Guiney in Africa give to their divinities. They have a fetish for each province, and a particular fetish for each family. This can be a tree, an ape's head, a bird, or something like that, following their imagination."("Fétiche, f, F. (Hist. mod) Nom que les peuples de Guinée en Afrique donnent à leurs divinités. Ils on une fétiche pour toute une province, & des fétiches particuliers pour chaque famille. Cette ici o est un arbre, une tête de singe, un oiseau, une quelque chose de semblable, suivant leur fantaisie" (D'Alembert and Diderot, 1751–1765: 598).) Their main source was the seventeenth-century Dutch geographer Dapper's *Description of Africa* (1686).

Interestingly enough, in this definition there is no reference to the fact that the term 'fetish' does not come from any African language, but from the Portuguese term, *feitiço*. This is the first misunderstanding: this is not an African term, but a European one. And yet, there is a significant shift between the *feitiço* and the *fetish*. The Portuguese *feitiço* is a magical event – a spell or charm, an act of sorcery; *feitiço* then is not exactly a divinity, but a magical action. The term itself has a long and interesting etymology: it comes from the Latin *factitius*, which means made up or artificial; from there comes the Medieval Latin *maleficium*, something said or done for or with magical effect. In fact, in Portuguese *coisa feita* ('something done') is synonymous with *feitiço* (Sansi, 2007). The *feitiço* was persecuted not only because it was evil, but also because it was a trick, a falsification. Originally, *feitiçaria* was more an object of Christian law than of Christian theology (Pietz, 1987: 31). In 1385 and 1403, King João I of Portugal made laws against it, in which he forbade his subjects to use or effect charms (*obre de feitiços*), bonds (*ligamentos*), or summoning up of devils (*chamar os diabos*), since *feitiçaria*, like idolatry, is inspired by the Devil. *Feitiçaria* is always an accusation; no one would admit to being a *feiticeiro*. But this official discourse on sorcery could be bypassed by the practitioner of magic affirming the contrary, that one was practicing magic against the Devil, not for it, and against the evil spirits that haunted living people. They could do this since it was not their techniques and instruments that constituted the *feitiçaria* but the inspiration from the Devil. This introduced a considerable ambiguity in its persecution.

The discourse of the *feitiço* arrived to the coasts of West Africa with the Portuguese in the fifteenth century. The Portuguese addressed the pagan practices of the Africans as 'idolatries and sorceries' (*Idolatrias e feitiçarias*) (Sansi, 2007). Idolatry would be a form of organized religion, but with false images of gods or 'idols' (Bernand and Gruzinski, 1988); *feitiçaria*, on the other hand, would not be organized religion, but individual practices of sorcery.

Where does 'fetishism' fit into this picture? The discourse of the 'fetish' and 'fetishism' emerges in the seventeenth and eighteenth centuries not in the writings of the Portuguese, but in those of other European travelers, essentially Dutch and Protestant ones like De Marees (1602), Dapper (1686), and

Bosman (1705). For these travelers, the *fetissos* were the gods of the Africans, and the *fetisseiros* were their priests. The reference to the Portuguese term is in most cases forgotten or, better, misrecognized. Misrecognition and disavowal are in fact central to the 'problem' of the fetish. As opposed to a discourse of idolatry, these travelers understood that Africans worshiped the objects themselves as gods, not as images (idols) of the gods. This was the radical novelty of the discourse of fetishism in relationship to idolatry: its 'untranscended materiality,' in Pietz's terms; the object does not represent a god, but it is a god itself.

Bosman made one of the more accurate accounts of the 'fetish.' According to this Dutch tradesman, Africans worshiped objects, like stones, trees, and even animals and artifacts. What was more surprising was that Africans recognized that they were 'found' by chance, that they made them with their own hands, and that they had as many as they wished (they were unaccountable). In other terms, they recognized that their gods were artifices made by them. The priests of these *fetissos* were the *fetisseiros*, inevitably defined as greedy, powermongering, and treacherous, manipulating the fear of the people for their own benefit. Bosman not only was scandalized by what he identified as the hypocrisy of the priests but also, in fact, thought that most people were quite aware of the fatuousness of their beliefs, but still they believed in the *fetissos*.

In Bosman's argument, we can identify some of the core issues of the problem of the fetish. First is the 'confusion' of creation and the creator: the Africans, for Bosman, worship things of their own making, instead of worshiping the creator who made them. Second, African religion is described as a form of 'trade' and exploitation by a priestly elite who manipulates the masses. Still, Bosman is very adamant to make clear that these masses are fully aware of their exploitation, but they accept it – again, the theme of misrecognition. Ultimately, Bosman's reading is also full of misrecognition; behind the construction of an 'African' other, it seems clear that the model he is attacking is much closer in space and time: the 'Papism' of the Portuguese who preceded Bosman and the Dutch in the African trade, and who still were their main enemies and competitors in the Atlantic world.

In fact, the problem of the fetish was not just one of religion but also one of commerce. For Bosman, the difficulty of trading with Africans was that they valued things irrationally, according to 'caprice.' The issue, then, was how to establish the terms of exchange between two radically different systems of value. Protestant European traders were particularly annoyed when they were obliged to make 'fetish-oaths' on the objects that Africans worshipped. The objects of trade themselves were also subject to this ambiguity and artificiality: European traders were particularly wary of 'fetish-gold' (Atkins, 1735: 183), or gold mixed with other metals.

Fetishism as a Countermodel of the Enlightenment

In the end, this is more a story of misrecognitions than misunderstandings. A theory of 'fetishism' emerged, built on these misrecognitions, but it was going to have crucial importance in the history of social thought. In *Du Culte des Dieux Fétiches*, Charles De Brosses (1760) finally developed a full-fledged theory of the *fetish* and invented the term *fetishism*. For De Brosses, the African fetish is not just a curiosity but also a general model at the origin of all religions – starting with Egypt. For De Brosses, the origins of religion are fear and need: 'savages' would worship unexpected events and beings that they couldn't understand and control, addressing them as persons with a will and power superior to those of humans – as gods. This is not a 'naturalism,' or a religion of nature, since fetishism doesn't have a notion of nature as opposed to the social or the supernatural. Fetishism confuses people with things, events with actions, the given with the made, and immanence with transcendence.

With his theory of fetishism, De Brosses organized the most powerful argument against religion in a century of skepticism. By identifying the worship of things as the first step of religion, it was finally possible to integrate the criticism of religion to a general theory of progress, which would see the Enlightenment as the last, logical end of human achievement: in modern Europe, men had finally managed to relate to things just in the terms of science, as objects of natural law, or in the terms of the economy, as commodities with a market value, separate from any religious prejudices and fears. Religion, science, and economy would be finally separated, in what Bruno Latour (1993) has called a process of 'purification' separating their religious beliefs from material things altogether.

By the same token, the African fetishists would be seen as the more primitive and abject of men. For Kant, the cult of fetishes "is so disgraceful that it seems to contradict human nature. A feather, a horn, a shellfish or any common thing, just being consecrated with some words, becomes an object of veneration invoked in oaths. The Blacks are extremely vain, and so loud that they have to be dispersed with a stick" (Kant, 1960: 111). Hegel thought that Africans 'adored the first thing that comes their way' arbitrarily; this was the reason why, for Hegel, fetishism was not even a form of religion, since the fetish was not even an object of religious worship: fetishist Africans lived in a moment prior to history, since they lacked "the principle which naturally accompanies all our ideas – the category of Universality" (Hegel, 1956: 93). Africans were slaves of chaotic contingency, or, better, of the false priests who mediated this chaos.

The 'purification' of religion from science, and of people from things, was also a geopolitical process of the separation of 'modern' Europe from fetishist Africa. As a matter of fact, the development of a theory of the fetish was essential for the very construction of this very model of European modernity, since it offered a perfect model of what an 'impure' humanity would look like. In these terms, the theory of *fetishism* in the social sciences as an elementary, and mistaken, form of materialism persisted during most of the nineteenth century. The main example is Auguste Comte (2001), who still defined as 'fetishism' the first stage of religious worship, before polytheism and monotheism. But by the end of the nineteenth century, with the emergence of social anthropology, the use of the term started to be questioned and replaced by other theories. Tylor (1874) subsumed 'fetishism' under his own theory of 'animism,' stating that the object of worship of the fetish was a spirit contained in the object, not the object itself. In other terms, he basically questioned the very notion of the

fetish as a radically material entity. More than based on specific empirical evidence, we should understand Tylor's questioning of the notion as an attempt to redeem the 'primitive' from their banishment outside history and human nature by Kant and Hegel. For the Western tradition, the very distinction between body and spirit, and between object and subject, is at the basis of human reason, and Tylor, as the founding father of anthropology, was keen to demonstrate the psychic unity of humankind, and the basic evolutionary capacities of all humans on these grounds. Fetishism, in these terms, is not just irrational but also outside of reason itself. To recognize the irredeemable materiality of the fetish would question the whole enterprise of a unified description of humanity based on shared reason.

Durkheim, the other founding father of both anthropology and sociology, took a very similar stance. From a Durkheimian perspective (1912), the problem of elementary religion starts with the very issue of representation – the capacity of understanding something beyond immediate sensory perception and individual existence; and this capacity is common to humanity as a whole. But the answer to this question for Durkheim is not animism but totemism: the basic issue is not the distinction between body and spirit, but the representation of a collective entity beyond immediate experience.

Fetishism as Cultural Critique

Mauss's rejection of the fetish as an enormous misunderstanding follows Tylor's and Durkheim's humanistic approaches – denying the very possibility of fetishism, and the accusations of irrationality and even inhumanity addressed to non-Western peoples. Paradoxically, by the time that anthropology was rejecting fetishism, the very notion had also been used critically against the West by some of its major contemporary thinkers, Marx and Freud. Marx's brief but powerful parable of 'commodity fetishism' reverts to the basic parallelisms between religion and commerce that were at the center of the Dutch traders' questioning of the African fetish. For Marx, instead, it was the very Western form of commodity value that could be understood as fetishism (Marx, 1992). Marx noticed that same mechanism the European travelers attributed to African fetishists: people in capitalism make commodities with their own hands, but then misrecognized that the value of these commodities was the result of their own making; in contrast, it is thought that commodities have value in themselves. Freud's use of the notion of the fetish (Freud, 1927) would also impinge on the question of misrecognition, or, in more psychoanalytical terms, disavowal. For Freud, the sexual fetish is a thing that becomes a surrogate object of desire, in replacement of the actual object of desire, which is repressed. This object emerges out of the event of an encounter, which the fetishist tries to recreate in his or her fantasies.

Marx's and Freud's approaches involve a clear emphasis on misrecognition and the repression or hiding of the truth of interpersonal relations behind objects, which are falsely endowed with a power that they don't have. The combined influence of these authors has been crucial in the twentieth century, and the critical theory of the fetish has been a tool for many modern authors. In the social sciences, Pierre Bourdieu is probably the most well-known proponent of this critical theory of fetishism, as applied to the field of art, for example (Bourdieu, 1992). Bourdieu describes the field of art as sustained in a collectively held *illusio* (an embodied belief) of the autonomous value of art. This *illusio* involves a misrecognition not only of the interdependency between art and other forms of social value, but also, essentially, of the artificiality of this value itself. Like the African fetishists of Bosman, Bourdieu's artists are perfectly aware that they have made their fetishes with their own hands, and yet they adore them as if they had an autonomous power.

Michael Taussig's *The Devil and Commodity Fetishism in South America* (1980) is probably one of the more original contributions to the literature on the fetish. Taussig described how the people of a Colombian valley read the arrival of modern capitalism and the money economy through traditional discourses on magic. In Taussig's terms, this was not a misunderstanding of capitalist production, but rather the opposite: an explicit description of the mechanisms of commodity fetishism that were misrecognized in Western ideology. Taussig's argument was a precedent to a growing ethnographic interest in the 1990s in what came to be called 'the magic of modernity' (Comaroff and Comaroff, 1993; Geischere, 1997; Meyer and Pels, 2003): many anthropologists, particularly in Sub-Saharan Africa, were witnessing an upsurge in magic accusations and beliefs. Rather than interpreting this phenomenon as a 'return to tradition,' many of these authors perceived it as a local adaptation to the global commodity fetishism of capitalism at the turn of the twentieth century. Only recently, though, have some authors started to think about this phenomenon in a longer historical and conceptual framework, showing how this 'encounter' with globalization is part of a very long process of exchanges, starting with the very origins of the term 'fetish' (Sansi, 2011).

The Untranscended Materiality of the Fetish

Independent scholar William Pietz made a major contribution to the literature of the fetish in a series of articles published in the late 1980s with the title "The Problem of the Fetish" (Pietz, 1985, 1987, 1988). Pietz offered an encompassing historical account of the term, emphasizing that it was the result of a very specific space and time: the coasts of West Africa in the seventeenth and eighteenth centuries. According to this author, 'the problem' could be defined around four fundamental questions – *personification*, *territoriality*, *historicity*, and *reification* – which we should address with some detail.

First is personification. Fetishes are intensely personal objects (Pietz, 1985: 11): they add to the person, as for example in the case of amulets worn on the body to protect it from attacks. By the same token, parts of the person, when stolen or found by enemies, can also be used in sorcery. This is a form of distributed personhood, as Gell has noted (1998), although it is based on negative reciprocity: a distributed person has to avoid leaving dispersed pieces of his or her self, to avoid the risk of sorcery, and has to add to the body elements that can act as shields. But of course, to make these

shields work one has to give a part of one's self to them, as an offering in a mediated exchange between person and thing: the fetishes have to become a part of the person, not just instruments or technological devices. That is why other people cannot use a person's own fetish: because they are a part of the self.

The life and the value of the fetish, however, cannot be solely understood as an extension of the personhood of humans: it is also a result of its territoriality and historicity. On the one hand, the 'untranscended' materiality of the fetish, which is not just a symbol or icon of a divinity but also a 'self-contained entity' with an active force, introduces the question of the position of the object in space and time as a 'territorialized' (Pietz, 1985: 12) object. The 'life' of the fetish is conditioned by material constraints, in space and in time: its inability to move physically, which makes it strictly dependent on its human associates, and its inscription in a concrete and specific place where it is protected, like an altar or a body.

But these are not the only ways in which materiality influences processes of value: in contrast, Pietz notes that "the fetish is always a meaningful fixation of a singular event; it is above all a 'historical' object, the enduring material form and force of an unrepeatable event" Pietz (1985: 12). The radical historicity of the fetish, which emerges from a unique event, is what most disturbed Hegel, and what convinced him to put Africa out of history. What was interpreted as 'caprice' or 'arbitrary' choice is, in fact, the recognition of the singular values generated by events, which cannot be explained by the list of elements that make a part of the situation before they happen (Latour, 2001: 131). Finding a fetish is an event that cannot be predicted: it is a single happening in which people find something unforeseen that they recognize as a part of themselves, something that becomes personified. Pietz explains this point wonderfully by making reference to Leiris and the surrealist notion of the *objet trouvé*: "these crisis moments of singular encounter and indefinable transaction between the life of the self and that of the world become fixed, in both places and things, as personal memories that retain a peculiar power to move one profoundly" (Pietz, 1985: 12).

This historicity founded in events is radically different from that of Hegelian history, as teleology. The event in which the fetish is found is not perceived by the person as arbitrary, but necessary. The value that the person finds in the object is not randomly attributed by the person, but it is seen as an *immanent* value of the object, something inchoate that was always there, waiting for this particular person, something that he or she recognizes. It is as if the thing was offering itself to the person – as if they always belonged together. In this sense, this is a process of mediated exchange, between the person and a hidden value that is giving itself to the person. Thus, contextual values and historical changes are perceived as immanent values and mediated exchanges.

The last point that Pietz raises is 'reification.' The fetish, for Protestant European travelers and Enlightenment philosophers, raised the question of the relative value of objects: values were not universal, but dependent on a "particular order of social relations, that in turn, they reinforce" (Pietz, 1987: 24). This leads to a questioning of contextualizaton, or, as Pietz puts it, of 'reification': how values attributed to objects are in fact constructed by humans. Of course, 'reification' is always an accusation: it is the others who reify, who think, through a process of disavowal, that objects have intrinsic values. Thus, the identification of a system of value with fetishism is an accusation of a false ideological projection, a false consciousness. Stemming from the critical and skeptical definition of De Brosses, the accusation of fetishism became an extreme form of criticism of ideology.

The first three questions that Pietz identifies – territoriality, historicity, and personification – are relatively independent from the problem of reification; they are central to the formation of the notion of the fetish in early colonial West Africa, while the problem of reification was raised later, in the radical criticism of the fetish by Enlightenment philosophers, in the formation of a theory of fetishism. There is a fundamental difference between the two moments: the first is a moment of intercultural mediation, in which the notion of the fetish emerges in a sphere of exchange; the second is a moment of differentiation and alienation, when enlightened Europeans try to make clear what makes them different from and superior to Africans (and, by the same token, the Portuguese).

Pietz's work inspired a revival of literature on the fetish, developing some of the different lines of his argument: some were closer to a more traditional reading of fetishism as cultural critique (Apter and Pietz, 1993), and some more interested in the radical historicity of the fetish as an object of cultural exchange (Spyer, 1998). The possible yet contradictory ways of approaching the 'problem of the fetish' could be exemplified by two radically different readings of Pietz by two contemporary authors: David Graeber (2005) and Bruno Latour (2010).

Graeber: Fetishism as Social Creativity

The central argument in Graeber's reading of Pietz is a defense of fetishism as social creativity. If fetishism, at root, is our tendency to see our own actions and creations as having power over us, how can we treat it as an intellectual mistake? The bad reputation of fetishism is a result of a misunderstanding. Africans would 'make' fetishes as a means of creating social relations. They wouldn't hide the fact that the objects, like the social relations that depended on them, were 'made up' and thus were, in a way, arbitrary. The Europeans, however, would not recognize that the value they gave to objects was the result of a social relation: it would be the Europeans who would misrecognize (or disavow) the social construction of reality, as it were, giving it a bad name: fetishism. In Graeber's reading, Europeans and Africans shared a certain existential pessimism: both see society and its institutions as necessary evils that have to be institutionalized to prevent chaos. The Europeans and the Africans were not that different, but in fact were all too similar. For Graeber, "it was the underlying affinity, I suspect, which accounted for the common European reaction of shocked revulsion and dismay on being exposed to so many aspects of African ritual: a desperate denial or recognition" (Graeber, 2005: 415).

Graeber is underscoring one of the four problems identified by Pietz: the problem of reification – how social values are

a social construction. Graeber insists upon the fact that there is nothing abnormal or stupid in using objects as the objectification of social relations, and that this process of objectification is ultimately arbitrary. It is not the object, but the action made upon it, that gives it social power. For Graeber, objects are "only the medium. Hence what they are is ultimately somewhat arbitrary: one case valuable objects from faraway lands, or one can, in fact, use pretty much any random object one lays one's hands on, 'a Lion's Tail… a Bird's Feather… a Pebble, a Bit of Rag.' In this, Pietz's sources had a point, because this is exactly the moment where the arbitrariness of value comes fully into focus. Because really, creativity is not an aspect of the objects at all, it's a dimension of action. In this sense the new does in fact emerge from the old, and the numinous, alien nature of the object is really the degree to which it reflects on that aspect of our won actions that is, in a sense, alien to ourselves" (Graeber, 2005: 425).

The first question to ask here is if these 'Africans,' who Graeber, Pietz, and their sources invoke, would really agree with this idea of creativity. Would they say that, really, the power they recognize in objects is of their own making? It seems like Graeber falls back into the European *understanding* of the problem of the fetish. The power of objects is not just the result of a process of reification, of imposition of human value. The power of the fetish, or these objects that the Europeans identified as 'fetishes,' is not *arbitrary* but *necessary*. The power of the fetish is not arbitrarily attributed by the person who finds it, but is recognized by this person as inherent to the object. This power, however, is only revealed in the encounter of the object and that person. In that sense, we could say, it emerges in and by this encounter. It is not "any random object one lays one's hands on, 'a Lion's Tail… a Bird's Feather … a Pebble, a Bit of Rag,'" but it *must* be, and it *could only* be, that Lion's Tail, that Bird's feather, that pebble, or that bit of rag that is found at that specific moment and at that specific place, which unveils the uncanny power of the fetish over the subject. It is not irrelevant, in this sense, that this object has an 'alien nature.' It is precisely its alien nature – its radical alterity – that awakes the shock of recognition. That connection of subject and object, and of space and time, is not just an action by which the subject infuses the object with his or her creativity, but is an event of encounter that brings about something else, something that was not present before the encounter. This encounter, in other terms, has a historicity. Historicity, as we have seen, is one of the central questions that the problem of the fetish creates for Pietz, and, in many ways, it is irreducible to reification.

Latour and the Factish

Latour's *On the Modern Cult of the Factish Gods* (2010) was also written as a follow-up to Pietz's 'The Problem of the Fetish' articles. But we should also read it as a follow-up to his now classical pamphlet, *We Have Never Been Modern* (1993), where he takes on the question of the great divides of modernity – the 'purification' of society from nature, and of people from things. The emergence of the problem of the fetish is crucial in this process of purification, as a first instance when European traders and slave mongers explicitly accused Africans of confusing nature with culture, cause with consequence, people with things, and the product with the producer. Latour argues that it was the construction of this African counterexample that actually helped the Enlightenment objectify these distinctions, essentially the distinctions between nature and culture, between natural law and human convention, and between 'fact' and 'fetish.' According to the European slave mongers, Africans worshiped the things they made with their own hands. That wouldn't be such a surprise for a cynical, Western, freethinking slave monger who wouldn't necessarily believe in God or religion: all religions were made by men, since gods don't really exist in 'nature' – they are not facts. But still, all religions would hide the construction of the gods: priests would keep the masses in ignorance of this construction. Africans, on the other hand, as Graeber says, were explicit about this construction. In these terms, religions would be described basically as mechanisms of social power, using fetishes as puppets through which they could control the ignorant masses. This, in the long run, became a general theory of society as opposed to nature. Nature would be based on facts, given things that happen in the world, and would respond to natural laws independent of the intentions of humans. Society, on the other hand, would not be based on facts but on fetishes, made-up things that happened only within humans responding to human intentions – their will to power. Fetishes, as opposed to facts, would not exist autonomously from humans; they would be just intermediary entities used to veil the agency of humans. This is an extremely powerful theory, and it has survived for 300 years: as we have seen, Bourdieu's use of the term 'fetish' in his writings on art is quite consistent with these notions. This is what Latour (1993) calls the 'antifetishist' tradition, which sees social institutions as fictions hiding the 'facts': in general terms, the social domination of some humans over others. Latour wonders if it is possible to overcome this distinction between social fictions and real facts, going back to the roots of the problem of the fetish, to overcome theories that reduce processes of objectification to fetishism, alienation, disavowal, and misrecognition. This is an important point: saying that values are attributed to objects through processes of objectification, and that these processes are culturally relative, is not the same as saying that all attribution of value to objects is a false projection that hides a will to power. This is a point on which Pietz is not clear when he reduces objectification to reification.

After all, the so-called African fetishes inspired the foundations of a great deal of modern European social theory, anti-fetishism. Still, what was shocking for Europeans about Africans was not so much that they believed in fetishes, since this was the very essence of social life everywhere. What was shocking is that they didn't hide their fetishism! They acknowledged they made their fetishes with their own hands, and they recognized they were artifacts. But for Latour, as opposed to Graeber, this doesn't mean that Africans were explicit 'fetishists.' In contrast, it means that they didn't really make a distinction between facts and fetishes, 'real' and 'invented' things: they really thought that they were autonomous entities with their own agency, not

just because they had made them. Latour called this hybrid of fact and fetish the *factish*.

Latour proposed to reverse social theory from this point: what if 'Africans' were right? What if it doesn't make sense to distinguish between fact and fetish, things given and things made, natural reproduction and human production, and nature and culture? What if what is counterintuitive, strange, and irrational are all these distinctions, and not the confusion between these distinctions? Starting from here, Latour's program for a social science is not to reveal the hidden truth of the artifice of social life dissecting fact from fetish, looking for the dark secrets of human nature, but to follow the *factish*, as it were, to see how things are made into autonomous entities with their own agency.

Is Latour, then, rehabilitating the much criticized notion of the fetish? His position is quite ambiguous because of his development of a third, hybrid term, *factish*. The basic point that Latour was making is that we have to acknowledge the possibility of thinking about agency beyond the human, beyond classical Western distinctions between nature and society and between people and things, and beyond all the oppositions we have inherited from the tradition of Western thought since the Enlightenment. In any case, we could say that if Graeber stresses one of Pietz's arguments, the one on reification, Latour stresses the argument on historicity, the recognition of the emergence of new agencies generated by events, which cannot be reduced to the list of elements that make up situations before they happen (Latour, 2001: 131).

Conclusions: From Fetish to Fetishism and Back

To conclude, it is important to make clear that the question of fetishism is slightly different from the problem of the fetish. As we have pointed out in this article, the discourse of fetishism is basically built upon the idea of reification – the confusion of human values with the values of objects, and the subsuming of relations between people to relations between people and things. The discourse of fetishism as misrecognition, disavowal, ideology, and false consciousness has been central to social thought from De Brosses to Bourdieu and beyond. The problem of the fetish is slightly different, since its starting point is not a general ideology that attributes power to objects (fetishism), but it starts from a radical singularity, the 'historicity' and 'untrascended materiality' of the particular event of the encounter in which a specific agent is formed. The 'fetish' is not a token of a general type; it does not *represent* anything else, but it is always a radically new entity, grounded on a specific place and time, and is inredeemably material. One can think of 'fetishes without fetishism' (Pouillon, 1975): there are particular instances and events of the fetish that do not require being subsumed under a general ideology of fetishism, such as African religion, modern capitalism, or modern art. In general terms, the very notion of the fetish is also radically historical and territorial: it is the result of the encounter of West Africans and Europeans in the wake of colonialism. In the future, it may be interesting to explore a bit further these dimensions of the problem of the fetish, besides the discussion of fetishism and reification, which has been at the center of attention for so long.

Feudalism

Abstract

Feudalism has a wide variety of meanings. Traditionally it refers to the sociopolitical order of Western Europe in the central and later Middle Ages (*c*.900–1500), though it has also been used to characterize premodern Asian and African societies displaying similar features. The nature and relevance of feudalism as a model has been a subject of much debate and it is important to distinguish between three distinct (though broadly related) understandings of the term: the Marxist conception of feudalism as an economic system based on the 'feudal mode of production', the social historical model of 'feudal society' as something approximating a Weberian ideal type, and the legal definition of feudalism as a form of service tenement based on the fief.

Feudalism is a subject of enduring interest to historians, sociologists, and economists. Although definitions vary widely, the term generally designates the socioeconomic order of Western Europe in the central and later Middle Ages (*c*.900–1500). Feudalism has been the subject of intense debate and it is important to distinguish broadly between three models of the phenomenon (which amount, in effect, to different definitions of feudalism): the Marxist or historical materialist, the social historical/sociological, and the legal-tenurial (see Wickham 2001). Each of these is based on different premises, though all purport to describe aspects of European society in the Middle Ages.

Feudalism: The Noun and Its Derivation

Feudalism derives from the Medieval Latin *feudum* (plural: *feuda*), referring to a form of conditional land-tenure. *Feudum* is generally rendered into Modern English as 'fief' and is believed to derive from the Proto-Germanic **fehu*, which originally meant cattle (cf Modern German *Vieh*), though it also came to have the broader connotation of 'wealth' or 'property' (cf Modern English 'fee') (Arcamone, 2001). As an abstract noun feudalism makes its first appearance in English in the nineteenth century, when it began to be employed as an equivalent to the French *féodlité*, which is attested about a century earlier. As originally employed, feudalism refers to a tenurial system based around fief-holding. It continues to be used in this (strict) legal sense, as we shall see, but has also taken on broader connotations.

The Legal Model: Feudal Tenure and the 'Feudo-Vassalic Contract'

The pioneering work on feudalism was undertaken in eighteenth-century France. Within this context, the term (French: *féodalité*) was used to characterize the tenurial structure of the *Ancien régime*; feudalism was seen as the system of land holding, which evolved during in the Middle Ages. This legal-tenurial model of feudalism continues to be employed by historians and is sometimes termed feudalism in the 'strict' sense, since its places a strong emphasis on fief-holding as its defining characteristic (see Ganshof, 1961: pp. xv–xviii). In some languages this model is even distinguished from its other socioeconomic counterparts. Thus in German *Lehnswesen* denotes feudalism in a legal sense, while *Feudalismus* is preferred for other models, and in Dutch a similar distinction is made between *leenstelsel* and *feodalisme*.

According to the legal model, feudalism is characterized above all by feudal tenure: it is a system of land holding based on fiefs or benefices (*beneficia* (singular: *beneficium*): the latter term predominates in sources before the eleventh century), a form of conditional tenure, generally for one or more lifetimes. For tenure to qualify as truly feudal, however, the tenant must not only hold his land as a fief or benefice, but also be the vassal of his landlord. Thus feudalism combines a tenurial agreement with a social bond (in the technical language of feudal law these are referred to as 'enfeoffment' and 'vassalage' respectively). Traditional teaching holds that enfeoffment and vassalage were originally distinct, but came to be associated in the course of the seventh and eighth centuries, when the powerful Carolingian dynasty came to prominence in mainland Europe. This period saw much infighting within Francia (a region encompassing much of modern France as well as parts of Germany, the Low Countries, Switzerland, Austria, and northern Spain) as well as the rapid expansion of the Frankish realm from 751 onward. As a consequence – so the traditional wisdom – vassalage and fief-holding became associated: in order to attract ever larger numbers of warriors, the Carolingian rulers rewarded their followers with temporary landholdings in the form of benefices (generally taken from the Church). The result was that benefice-holding (or enfeoffment, as it would later be known) became related closely with vassalic status, eventually leading to the unification of the two phenomena (Ganshof, 1961: pp. 16–50, esp. 16–19; Mitteis 1933: pp. 521–524). This 'union of fief and vassalage', of a tenurial agreement and a personal bond of lordship, was the foundation of European feudalism. Although this first emerged in the Frankish heartlands, it was soon exported across the rest of Western Europe by means of conquest and settlement.

This form of tenure in exchange for service was defined by two rituals, homage and investiture, relating respectively to the

two elements of the feudal relationship (the personal and the tenurial). The first forged the bond of service: by placing his hands within those of his lord and swearing fealty a man became a vassal. The second, which generally followed on from the first, enacted the property transaction: by handing over objects symbolizing tenure and service (often swords, spears, or banners), the lord invested his vassal in his fief or benefice. Together these acts created the so-called feudo-vassalic contract (Mitteis, 1933: pp. 481–518; Ganshof, 1961: pp. 70–72 and 133–142; Le Goff, 1980). There were important consequences of this for both sides: henceforth the lord could expect loyalty and service – the 'advice and assistance' (*consilium et auxilium*) mentioned in many contemporary texts – from his man; the vassal, on the other hand, could anticipate receiving support and protection from his lord. In theory, if either party failed in its obligations, then the contract was dissolved and the property reverted to the lord. The contract also came to an end upon the death of either party. In the early days of feudalism, the lord might then enfeoff a new vassal; however, fiefs had a tendency to become inheritable and from the late ninth century what tended to happen was that homage and investiture would be repeated whenever lord or man died (what in German is termed *Herrenfall* and *Mannfall*). In this manner the fiction of the fief's reversion to the lord was retained, while the rights of the vassal's heirs to inherit were respected. In some parts of Europe heirs also had to pay a special due in order to inherit (a 'feudal relief'); nevertheless, the expectation of inheritance was generally strong (Mitteis 1933: esp. 135–146; Ganshof, 1961: esp. 133–139; cf Bonnassie, 1991: pp. 172–174).

The strength of this model of feudalism lies in its precision: it is possible to test for the presence of fiefs and vassalage empirically. Its greatest danger, however, lies in its prescriptiveness. The scholars responsible for it, above all the Belgian historian François Louis Ganshof and his German counterpart Heinrich Mitteis, tended to see feudal tenure in very legalistic terms. As a consequence, they frequently imposed modern tenurial and legal clarity onto affairs which were less formalized (indeed, in their work both scholars were forced to acknowledge many 'anomalies' and 'regional variations'). More problematic, however, is the premise on which this model rests: namely, that benefice-holding and vassalic status coalesced in the eighth and ninth centuries. As we shall see, there is good reason to doubt that this took place (at least so early). Rejecting such an early unification of fief and vassalage has significant implications. Whereas Ganshof and Mitteis treated feudalism as an early medieval phenomenon, treating the development of rights of inheritance and the multiplication of vassalic bonds as signs of the weakening of this system in the central Middle Ages, it now seems that these latter phenomena an integral part of feudalism from the start. As a consequence historians increasingly see the central and later Middle Ages as the heyday of feudal tenure, rather than as a period of decadence and decline (Carpenter, 2000; Spieß, 2009, 2013).

The Marxist Model: The 'Feudal Mode of Production'

As noted, beside the legal there are two other distinct models of feudalism: the historical materialist (or Marxist) and the social historical. These are broadly similar, insofar as they both treat feudalism as more than a form of tenure. Nevertheless, they are based on very different premises: the former on a Marxist understanding of society and economy as being shaped by distinctive 'modes of production', and the latter on a more sociologically inspired understanding of societal 'ideal types'.

The defining feature of feudalism in the Marxist sense is the so-called feudal mode of production. According to Marx, a mode of production (German: *Productionweise*) is defined by productive forces (encompassing both human labor and tools and technology) and relations of production (the societal relations governing production). Marx postulated a number of different modes, the most important of which within this context are the slave (or antique) mode, the feudal mode and the (early) capitalist mode, each of which succeeded one another in Western Europe between Roman antiquity and the Early Modern period. In all of these modes agriculture is the main source of surplus; what distinguishes them is the means by which this is generated: in the antique mode it is slave labor which underpins production, in the feudal mode it is peasant tenant labor, and in the capitalist mode it is wage labor. Any society can therefore be considered 'feudal' in a Marxist sense if production within it is defined by the work of peasant tenants. One of the salient features of societies dominated by the feudal mode is a tendency for competition to emerge between central authority and the ruling classes (often in the form of a struggle between center and periphery); since the latter derive their wealth from the same sources and in the same manner as the state, centrifugal tendencies are common, though by no means inevitable (see, with different emphasis, Anderson, 1974; Haldon, 1993).

Although Marx was relatively uninterested in precapitalist modes, a rich literature has developed on the theme. The greatest problem here has been distinguishing between different modes, and these debates have important implications for our understanding of the feudal mode. Hence, though the feudal mode is often presented as a preeminently European and medieval phenomenon (e.g., Anderson, 1974), some now prefer to define feudalism more broadly, treating any society in which surplus wealth is generated primarily by peasant labor as feudal (Haldon, 1993; Wickham, 2005: pp. 259–261; 2008). Seen in these terms, the feudal mode is the most common precapitalist mode, which is attested not only in medieval Europe, but also across much of Asia and Africa before the modern era. Indeed, it has been suggested that we would do better to speak in terms of a 'tributary' rather than 'feudal' mode for this reason (Haldon, 1993: pp. 63–69 and 91–92). Though many societies may qualify as 'feudal' in this sense, important distinctions can be discerned among them. Chris Wickham points to the extraction of surplus in the form of rent and services rather than taxation as the defining feature of medieval European feudalism (Wickham 1984; Wickham, 2005: pp. 56–62; cf Blank, 2013). However, it is precisely the variety witnessed within the feudal mode thus conceived which has led some commentators to call for a more restricted usage of feudalism within Marxist analysis. Jairus Banaji, in particular, argues that feudalism is in danger of losing its explanatory force when defined so broadly, suggesting that such work underestimates the differences between medieval

European feudalism and other tributary forms of society (Banaji 2010: esp. 181–250).

Sociological Models: Feudal Society and the *Annales* School

Perhaps the most widely employed model of feudalism is the sociological or social historical. Feudalism in this sense has been studied most diligently by historians of the *Annales* School, whose approach takes inspiration from sociology, treating feudalism something akin to a Weberian 'ideal type' (Wickham 2001: pp. 34–41). The starting point for this work was Marc Bloch's monumental *La société féodale* (Bloch, 1962 (first published in French in 1939)). Within this work, Bloch aimed to present rather than define feudalism and it was only after having completed his two-volume survey that he felt in a position to summarize its salient features: a subject peasantry; the prevalence of the service tenements (fiefs); the dominance of a warrior aristocratic class; the prominence of personal ties of obedience (vassalage); the fragmentation of public authority; and the survival of other (earlier) forms of association (Bloch, 1962: p. 446). Another important feature of feudal society was manorialism, though this was not a defining characteristic thereof. Like historians of feudal tenure, Bloch saw this society as a preeminently Frankish phenomenon; however, unlike his more legally minded counterparts he did not believe that the history of feudal society could be reduced to the story of one form of service tenement (viz, the 'feudo-vassalic contract'). According to Bloch, feudal society developed in two stages, neither of which could be defined by tenurial developments alone: a first feudal age, from the late Carolingian period up until the eleventh century, and a second, from the mid-eleventh to the thirteenth century. The first age witnessed the development of a feudal society: in the face of invasions by Vikings, Muslims, and Magyars, centralized authority began to decompose, giving way to a more localized and fragmented society, in which interpersonal bonds and regional power structures were predominant. The second feudal age saw the maturation and eclipse of this society: in this period a true hereditary nobility established itself and chivalric values developed; however, at the same time multiple vassalage and rights of inheritance began to threaten the centrality of the feudal relationships and mentalities. Bloch's treatment of feudal society set the parameters from future work, particularly within the Francophone world. Particularly influential was his treatment of feudalism as phenomenon that embraced all of society, from the greatest lords down to the lowliest peasants.

The most influential subsequent contributions to the field have come from Georges Duby, who was a product of Bloch's own *Annales* School. Duby developed and challenged Bloch's arguments about feudal society in a number of respects. In particular, he placed a greater emphasis on regional studies than had his illustrious predecessor: whereas Bloch sought to generalize about feudalism across all of Western Europe, Duby's most influential publication was his detailed study of the society of the Mâcon in Burgundy from the ninth to the twelfth centuries (Duby, 1971 (first published 1953)). Duby also parted ways with Bloch in other regards. He saw the development of feudalism in very different terms. Rather than postulating a first and second feudal age, Duby argued that feudal society emerged both later and more rapidly than Bloch had appreciated. His study of the Mâcon convinced Duby that public justice and authority, represented above all by the comital court or *placitum*, continued to operate well up until 980, suggesting that the decomposition of central authority diagnosed by Bloch had yet to set in at this point. Then, however, during a brief and tumultuous period between 980 and 1030 this system gave way to the (privatized) seigneurial system of justice, which was characteristically feudal (Duby, 1971: pp. 137–148). Other important changes could also be detected in these years: the disappearance of traditional forms of slavery and emergence of a servile peasantry, the formation of the nuclear family, and the development of a knightly class, to name but a few. Numerous scholars of the 1970s and 1980s followed Duby's lead, tracing how and when similar transformations took place across other regions of France, Spain, and Italy. The result of was a relatively coherent model of sudden transformation, around the year 1000, which Duby termed a 'feudal revolution' and others referred to as the 'feudal mutation' (*mutation féodale*). Therein was sought the explanation for numerous developments, from the end of slavery, to the Peace of God (a movement aimed at curbing aristocratic violence), to the growth of heresy (Duby, 1980; Bonnassie, 1991; Poly and Bournazel, 1991; Bois, 1992; cf Toubert, 1973; Bonnassie, 1975–1976).

At their best, these models avoid the pitfalls of their legal and Marxist counterparts: they neither limit feudalism to cases of a certain form of tenure, nor do they generalize it to such an extent as to deprive it of all distinctiveness. Nevertheless, these models present their own dangers. In particular, the 'feudal revolution/mutation' paradigm risks reducing complex socio-economic developments to what often amount to monocausal terms, as we shall see. Moreover, the use of the term feudal to describe this society raises the semantic issue of what is distinctively 'feudal' about it, if not the usage of service tenements in the form of fiefs. Nevertheless, despite these and other objections, it remains common to designate the society of the central Middle Ages feudal, particularly within Francophone scholarship (e.g., Mazel, 2010).

Modern Criticism I: 'The Tyranny of a Concept'

The concept of feudalism has been subjected to much criticism, particularly since the 1990s. Within the Anglophone tradition this has tended to focus on two related issues: the theoretical problem of how (or whether) it is helpful to employ feudalism as a sociohistorical model; and the empirical issue of whether feudalism in the legal sense ever existed. It was the first of these that Elizabeth Brown first raised in her justly famous article of 1974. There she argued that the concept of feudalism had grown too nebulous to be a useful tool of analysis; 'feudal', she pointed out, was becoming little more than a synonym for 'medieval'. Feudalism was, therefore, at risk of becoming a 'tyrannous construct', which inhibited rather than enhanced historical research. Brown's core objection to the term was thus semantic, but her arguments also went much further. She pointed out that feudalism was often employed in a dangerously reified fashion within scholarship: historians wrote of it as if it had an

independent historical existence, rather than being one model (among many) for understanding medieval society. Her ultimate conclusion was that historians should avoid the term feudalism altogether and restrict 'feudal' as an adjective to cases involving fiefs (Brown, 1974: p. 1086).

Criticisms of an altogether more fundamental nature were raised by Susan Reynolds in her 1994 monograph *Fiefs and Vassals*. Although Reynolds framed her arguments as a development of Brown's earlier critique, her target was quite different. Whereas Brown's criticisms were directed above all at historians who used feudalism as a socioeconomic model (who had tended to be most guilty of expanding the term's semantic range), Reynolds' were leveled at those who used feudalism in a legal-tenurial sense. In a nutshell, Reynolds' thesis was that feudalism in this form had never existed. Her argument proceeded from the belief that the union of fief and vassalage, which as we have seen was the lynchpin of tenurial models of feudalism, never took place; although fiefs and vassals existed during the Middle Ages, they were never associated in the formalized and systematic manner postulated by feudal theory. As such, the 'feudal system' was not a medieval creation at all, but a chimera, invented by lawyers and historians between the later Middle Ages and Early Modern era. Reynolds argued that this model was born in two distinct stages. First, jurists of the central and later Middle Ages (especially those responsible for the *Libri feudorum*) began to systematize existing property relations into a more formal guise. Then, during the Early Modern period Francophone legal experts picked up these terms, further systematizing the evidence to hand in the process. Feudalism is therefore a product of two stages of modeling and systematizing and cannot be expected to conform to (or illuminate) property relations in the early and central Middle Ages.

Reactions to these lines of criticism have been predictably mixed. Brown's arguments have been taken as a salutary warning about the semantic growth of the term feudalism and subsequent scholarship has employed it in a more cautious and self-conscious fashion (e.g., Wickham 2001). Nevertheless, her more strident calls to abandon the concept have found few supporters (Reynolds being perhaps the most prominent). Reynolds' work, on the other hand, has occasioned stronger feelings. Elements of her thesis have been warmly received. In particular, her call for a more flexible approach to the legal culture of the early and central Middle Ages has met with wide approval. Her arguments about the unification of fief and vassalage have also achieved a degree of acceptance and most historians would agree that earlier scholarship erred in placing this development in the Carolingian period. Nevertheless, Reynolds' more bold claims have met with resistance. In particular, her belief that fiefs and vassalage were never closely associated has convinced few (Barthélemy, 1997; Deutinger, 2002). Similarly, her insistence that feudalism *tout court* was an Early Modern invention has not been widely accepted (Wickham 2001; White, 2005b; nos. XI–XII; Patzold, 2012: pp. 43–94).

Modern Criticism II: Feudal Transformation

Criticism of a different nature has developed regarding the shift variously called the feudal revolution or mutation. As noted, it was Duby's belief that feudal society emerged not in two stages, as Bloch had suggested, but in one rapid transition around the year 1000. In this he was joined by many prominent French historians of the 1970s and 1980s and in 1994 these voices were joined by that of the American scholar Thomas Bisson, who diagnosed what he saw as a sudden and revolutionary rise in lordly violence across Europe in the early eleventh century (Bisson, 1994). Since then, however, voices of dissent have been raised. Thus, in a series of provocative articles and monographs starting in 1992 Dominique Barthélemy has sought to dismantle almost all aspects of the 'Duby thesis'. Like Brown, one of Barthélemy's concerns was that fidelity to a particular model (in his case, of feudal revolution) was straightjacketing scholarship: work produced within this framework tended to ask when and how transformation took place, without questioning the very mutationist paradigm on which it was built. In response, Barthélemy argued for a return to something closer to Bloch's original model of feudalism: he suggested that the social and political landscape of France changed slowly and subtly between the early and central Middle Ages, starting in the ninth century and continuing through to the twelfth and thirteenth (Barthélemy, 1992, 2009). In this respect, he argued that many developments, which first come fully to light around the year 1000, were already taking place much earlier. The turning of the first millennium did not so much witness a sudden societal transformation, as an important shift in the nature of the historical evidence, a 'documentary mutation' (*mutation documentaire*), as Barthélemy has neatly termed it (Barthélemy, 1993: esp. 19–127; Barthélemy, 2009: pp. 12–36).

Barthélemy has not been alone. Concerns of a similar nature have been raised by a number of American historians since the 1990s. Foremost among these are Stephen White, Frederic Cheyette, and Jeffrey Bowman, all of whom have argued against the mutationist model. One of their main criticisms is that it depends heavily on an anachronistic distinction between 'public' and 'private', treating early medieval comital courts as public institutions, but viewing their seigneurial successors as purely private. Yet, when examined closely, the operation of these courts reveals many similarities. Therefore, while there may have been developments in judicial practice around the turning of the millennium, to many lords and litigants such changes were probably neither so self-evident nor so fundamental as the mutationist paradigm proposes (White, 2005a: no. IX; Cheyette, 2002; Bowman, 2004). Indeed, it has been pointed out that the model of rapid transformation around the year 1000 runs the risk of oversimplifying change, presuming an a priori relationship between disparate religious, social, and economic developments (Bowman, 2004: pp. 226–227). More specific criticisms have been made of the feudal revolution as postulated by Bisson. Here it has been pointed out that the evidence for a sudden rise in violence in the eleventh century is probably more apparent than real (like the changes in documentary form diagnosed by Barthélemy), reflecting not only the increasing volume of source material, but also developments in approaches to historical writing. In this respect, it is important to note that most of our sources were written by monks and clerics, who had good reason to exaggerate (if not invent) the novelty of the forms violence they experienced at the hands of laymen (White, 2005a: nos. II–III; 2005b: no. XIII; Mazel, 2005).

Such criticisms have been well received and the proposition that all of Europe (or France) underwent a sudden feudal mutation around the year 1000 is no longer accepted. Nevertheless, the dangers of taking criticism too far have also been noted (Wickham, 1997; Fouracre, 2005). Indeed, there is no denying the changes which took place between the early and central Middle Ages and some recent work risks presenting a rather too static a picture of society in these years (Moore, 2000). In this respect, the antimutationist model is in danger of becoming just as monolithic as the revolutionary model it replaced.

Overview

Although the criticisms of feudalism – be they of the concept *tout court* or of the models used to frame it – have often sought to renounce the term altogether, in practice they have led to renewed interest in the subject. In particular, the work of Reynolds and Barthélemy has inspired scholars to return to first principles, revisiting the evidence for fiefs, vassals, and the complex interplay between these in the early and central Middle Ages. There is an emerging consensus that it is unhelpful to speak of feudalism in anything other than a Marxist sense before the central Middle Ages. Historians working within a legal-tenurial framework tend to see feudalism a development of the eleventh and twelfth centuries (Deutinger, 2002; Hyams, 2002; Dendorfer, 2004; Dendorfer and Deutinger, 2010; Roach, 2012), whereas those employing more sociologically informed models continue to see the eleventh century as the period in which classically 'feudal' forms of lordship emerged, though they emphasize the gradual and complex nature of developments (Kosto, 2001; Mazel, 2010; West, 2013). It would, therefore, seem that while 'textbook feudalism' never existed as such, something closely approximating it did. The relationship fiefs and vassalage is a case in point here: although it seems unlikely that these were ever as systematically associated as traditional teaching holds, it is equally clear that a close connection between the two developed during the eleventh and twelfth centuries. In this sense, there is something of an emerging reaction against what is perceived to have been the hypercriticism of the 1990s. However, above all recent work underlines the flexibility and adaptability of feudalism – as Steffen Patzold puts it, there was not so much one 'feudalism' as many forms of feudalism in Europe during the central and later Middle Ages (Patzold, 2012: pp. 120–121).

Abstract

Paul Feyerabend (1924–94) was a philosopher who gained recognition for his views on science and the role of science in society. Feyerabend is best known for his epistemological anarchism, the critique of the privileged position of science in society, and his endorsement of relativism. He made several contributions to the history and philosophy of science by studying the incommensurability of scientific theories and pluralistic nature of science, offering a new interpretation of the Scientific Revolution. His critique of classical empiricism and formal accounts of rationality remains his legacy in social studies of science and contemporary philosophy of scientific practice.

Paul Karl Feyerabend (born in 1924 in Vienna, died in 1994 in Genolier, Switzerland) was an Austrian-American philosopher who gained recognition for his views on science and the role of science in society. Feyerabend is best known for his epistemological anarchism, the critique of the privileged position of science in society, and his endorsement of relativism. Within the history and philosophy of science he is regarded as one of the preeminent critics of the 'received view' of Logical Empiricism and, later, Critical Rationalism.

Feyerabend enrolled at the University of Vienna studying mainly physics and philosophy, receiving his PhD in philosophy in 1951. He studied with Karl Popper at the London School of Economics the following year. Because of dim prospective academic chances in Austria, he accepted a position in Bristol, UK in 1955. From there, he accepted a permanent position at UC Berkeley in 1959, which he maintained till 1990. While in California, he accepted temporary positions at universities around the world, including the 1980 tenure at ETH Zürich, where he resigned in 1991. He died of a brain tumor only a few years later, in 1994, near Geneva.

His academic contributions range over a wide array of areas and topics: In general philosophy of science, he introduced the concept of incommensurability of scientific theories and, building on Karl Popper's falsificationism, developed several arguments for theoretical pluralism in the methodology of science; he later severely criticized mainstream philosophy of science for its shortcomings. In epistemology, he developed a behavioristic account of basic sentences and constructively discussed several problems of empiricism. In philosophy of mind, he is known for proposing eliminative materialism as a possible solution to the mind–body problem. In analytic philosophy of language, he delivered an early interpretation of Wittgenstein's *Philosophical Investigations* and a metaphilosophical critique of linguistic analysis. In the philosophy of physics, he first criticized the so-called Copenhagen interpretation of quantum mechanics, but soon came to appreciate aspects of Niels Bohr's scientific work and was influenced by David Bohm. Closely related to his interest in physics, in history of science, he contributed studies on the early development of quantum mechanics, put forward a controversial interpretation of the establishment of Copernicanism in the sixteenth century, and wrote a series of studies tracking the rise of rationalism in the Western history of ideas. He also highlighted the similarities between the history of science and art history as historically interwoven crafts. Additionally, he wrote about dramatics, commenting on Bertolt Brecht and Eugène Ionesco, and in political philosophy developed liberal ideas founded on John Stuart Mill and libertarian thought.

Although his patchwork-like philosophical works and writing style defy any easy systematization, there have been a number of proposals identifying common themes in Feyerabend's work. For one, his early allegiance to Popper's Critical Rationalism has been interpreted as an attempt to develop a systematic model of knowledge acquisition, furthering falsificationism, while also taking his cue from Wittgensteinian ideas. His later philosophy is, then, the result of relinquishing such a model, while developing early arguments to unwarranted extremes and adopting postmodern views (Preston, 1997). On another account, disparate works of his can be coherently grouped as sophisticated critiques of cases he viewed as manifest or lingering examples of conceptual conservatism in philosophy and the sciences. On this view Feyerabend – in true skeptical fashion – lacked allegiance to particular philosophical positions, employing them only instrumentally as *ad hominem* arguments against specific cases of conservatism (Oberheim, 2006). A third account highlights the roots of his views in the Viennese tradition of scientific philosophy, giving particular prominence to his early philosophy and later defense of scientist-philosopher Ernst Mach. On this view Feyerabend remained a distinctive 'Viennese philosopher' throughout his life, who furthered views pertaining to the intellectual and scholarly tradition of Central Europe (Stadler, 2008). Related to this interpretative scholarship, a more evaluative perspective has advanced charges of irrationalism (Stove, 2006) and postmodernism (Preston, 1998) against his later work, as well as defenses against these charges (Farrell, 2003, 2001).

From a sociological point of view, his influence within academe has been twofold. Staying in close contact with Karl Popper and collaborators allowed him to interact with like-minded scholars, though increasingly pernicious group dynamics led him to distance himself from the Popperian school, thus breaking with foremost academic interlocutors based at the London School of Economics (Collodel, forthcoming). Feyerabend also felt intellectually at home with the Minnesota Center for Philosophy of Science, led by Herbert Feigl (Stadler, 2008). Starting in 1957, he submitted several of his ideas to interdisciplinary scrutiny at the Center,

contributing to his fame as a rising star in the philosophy of science. However, with the broad exposure of *Against Method* in 1975 his more provocative ideas were received overwhelmingly negatively in the field of analytic philosophy of science, leading to vitriolic responses by Feyerabend and to a separation from the field. All the same, Feyerabend continued to receive job offers in philosophy of science from prestigious universities, permitting him to work unconstrained from particular allegiances, though, lacking a definite community. His legacy in philosophy has been similarly limited by the fact that he supervised very few students. Curiously enough, while the discussion of his work in philosophy decreased, central ideas found in Feyerabend's work – such as the pluralism and disunity of science – became commonplace in contemporary history and philosophy of science and scientific practice (Cartwright, 1999; Dupré, 1995). With similar dynamics, debates about expertise, democratic decision-making, and epistemic justice play a central role in contemporary philosophy of democracy and public policy (Kitcher, 2011, 2003) and epistemology (Fricker, 2009), but rarely acknowledge Feyerabend.

The exposure of his ideas in disciplines other than philosophy grew all the same, leading to notoriety outside the academe. Feyerabend has been widely read and referenced as one of the main theoretical resources in the post-Mertonian sociology of scientific knowledge (SSK). Backing away from Merton's 'weak program,' the emergence of social studies of science found the epistemological critique of 'postempiricist' philosophy of science by the likes of Feyerabend, Thomas Kuhn, and Richard Rorty to be a congenial framework for their approaches to science. While Feyerabend did not take active part in this reception, both the later Feyerabend and SSK shared an interest in anthropological approaches and conceptualized the ethnologist's view as a model of inquiry for their own studies.

Scientific Philosophy and Methodology

Feyerabend's early philosophical efforts were directed at reworking empiricism into an antifoundationalist enterprise, in which rock-bottom experiential certainty is given up in favor of overall testability and comprehensive corrigibility. His philosophical proposals grew out of scientific philosophy, aided by empirical findings of the sciences, logical analysis, and a deflationary strategy applied to philosophical concepts, which prompted to reinterpret major concepts of traditional philosophy (such as 'observability' and 'realism') as public dispositions of cognitive agents. Feyerabend used this behaviorist strategy time and again to make philosophical terms accessible to empirical analysis, to subject them to pragmatic reasoning about means–end relations and, more specifically, to include the cognitive agent in a third-person perspective as a necessary component of a scientific account of empiricism.

The behaviorist strategy opens the way for a distinctive conception where methodological rules can be interpreted as behavioral norms for attaining given epistemic aims in science. This conception of philosophy of science presented a line of action to approach an issue in his philosophy: the distinctive role of decisions in science. Perhaps surprisingly, the early Feyerabend cherished the distinction between 'facts' and 'conventions' or 'conventional decisions' in science. The distinction may be understood as discerning matters determined by fact and matters underdetermined by fact, i.e., not to be settled by reference to matters of fact alone, and thus open to decision. While the distinction is usually employed to underline the factual, stable content of science, Feyerabend used it to stress how many instances are a matter of decision and, therefore, show the pliability of science by human volition. This, in turn, was mirrored in his philosophy of science, which, as scientific philosophy, was after all conceived as being modeled after science. Methodology both exploits this freedom and tames its potential arbitrariness by devising means to end relations between freely available epistemic aims and the constrained possibilities to attain them: which avenues lead to certain epistemic aims? The behaviorist account further fleshes out the means: how should scientists act in order to achieve a given epistemic aim?

Feyerabend's early methodological efforts are focused on empiricism and the testability of scientific theories as a fundamental epistemic aim of science. The earliest analysis of empiricist accounts of science, found in his dissertation (1951) and later developed in 1958 and 1962, targets foundationalist accounts in Logical Empiricism. His notion of testability crucially builds on Popper's notion of empirical content where the empirical content of a universal statement is given by the class of its potential falsifiers. The larger the class of potential falsifiers, the greater its empirical content and thus testability (or, in Popper's terminology, falsifiability). Several distinct topics discussed by Feyerabend, like realism and instrumentalism, theoretical monism and pluralism, incommensurability and conceptual conservatism, are tied together by a simple methodological question: which avenues directly or indirectly increase or decrease the testability of scientific theories? Even though these issues may not be settled by appeal to matters of fact, they can be settled methodologically: if one is an empiricist, he argues, exactly those avenues which increase testability should be adopted, while those views which decrease testability should be dismissed. (The important presupposition here is that these issues can be sharply determined by appeal to epistemic aims.)

Feyerabend's early criticism targets: theoretical monism, the view that the reduction (or elimination) of concurring scientific theories is an indication of scientific progress; instrumentalism, the view that scientific theories are only predictive devices; and conceptual conservatism, an umbrella term introduced by Oberheim (2006) to collect several arguments devised to constrain future conceptual development by appeal to allegedly stable structures of components of our knowledge and language. Feyerabend goes to great length to show that the adoption of these views indirectly or directly decreases the testability of scientific theories and should therefore be opposed by 'good empiricists' (Feyerabend, 1963). Conversely, Feyerabend presents distinct arguments to show that the adoption of theoretical pluralism, realism and allowing for radical reconceptualizations increase the testability of scientific theories. The following sections examine these topics in more detail.

Pragmatic Theory of Observation

In the late 1940s, within the Kraft Circle, Feyerabend became interested in the Vienna Circle discussion of the early 1930s concerning the question of the empirical basis of science. (This discussion, known today as the protocol sentence debate, appeared as written articles in the journal *Erkenntnis*.) The discussion revolved around the following problem: Supposing that empirical sciences can be understood as a system of sentences, how should the subset of basic sentences (usually observational statements) that are used to test further sentences (usually theoretical statements) be demarcated and characterized?

Feyerabend's contribution, which he dubbed a causal or pragmatic theory of observation, was first presented in print in 1958 and then in 1962, yet it was already developed in detail in his unpublished dissertation (1951). His contribution is a behavioristic account of basic sentences according to which sentences uttered by an observer under certain circumstances are public dispositions of that observer. Instead of relying on phenomenal certainty of experience by appealing to phenomenalist or sense-data epistemology, which he finds empirically and logically flawed, Feyerabend's account is explicitly cast to end the 'special' treatment of human observers, by putting them on a par with other scientific instruments, whose capacities have to be checked and calibrated like any other part of the scientific process. According to the pragmatic theory of observation, in order to assess whether the sentence uttered by an observer is an observation sentence, it is necessary to assess how reliably this linguistic disposition is correlated with the presence of some state of affairs that is being observed. Feyerabend's behavioristic proposal models epistemic agents as sensible measuring instruments, which under certain conditions react in a certain way – the utterance of sentences being one such reaction. "We arrive at an empirical theory," Feyerabend writes, "which resembles in many respects the theory of thermometers. […] The theory establishes how reliably we can infer that 'something' exists from the fact that this 'something' is 'immediately given' to an observer" (Feyerabend, 1951: p. 58). The theory tells us which conditions need to be fulfilled in order to establish a causal relationship between the utterance of an observer and some event.

It is important to notice that within Feyerabend's account sentences uttered by an observer are simple physical facts, not interpreted linguistic statements. Feyerabend's analogy to thermometers, or measuring devices more generally, is meant quite literally. According to the pragmatic theory of observation, human observers are measuring devices just like thermometers. Like a scale signaling a certain value in correlation with a certain event, observation sentences are an observer's reaction (signal) to a certain stimulus (event). Whether the observer was reliably trained to raise her hand, simply growl, or utter the sentence "There's a blue flower" in reaction to such a stimulus is unimportant at this stage. Thus these utterances can be reliable indicators that something exists, but they alone do not give any indication of what exists – they are not yet descriptions of some state of affairs. They become descriptions only when being used in a theory, which provides their interpretation.

This account of basic sentences was extensively employed in Feyerabend's later papers under the label 'pragmatic theory of observation': "An observation sentence is distinguished from other sentences of a theory not by its content but by the cause of its production, by the fact that its production conforms to certain behavioral patterns" (Feyerabend, 1962: p. 36).

Theoretical Pluralism

Theoretical pluralism is the view that the proliferation of concurrent scientific theories is conducive to scientific progress and a sign of good scientific practice. Feyerabend thus counters the view that an ever growing limitation of concurrent theories is, instead, an indication and a desirable feature of scientific progress. This view, theoretical monism, figures in many accounts that view scientific progress as an advancing approximation to the one true theory. But Feyerabend also found the same view to be implicit in less idealized and more historical accounts, like Kuhn's *Structure of Scientific Revolution*, where theoretical monism is inscribed in the notion of paradigm, the necessary context in which normal science occurs. This aspect prompted Feyerabend to severely criticize Kuhn's model (Feyerabend, 1970a; Hoyningen-Huene, 2006).

The basic tenet of Feyerabend's theoretical pluralism is the *principle of proliferation* that scientists willing to increase the testability of established theories ought to "invent, and elaborate theories which are inconsistent with the accepted point of view even if the latter should happen to be highly confirmed and generally accepted" (Feyerabend, 1965: pp. 223–224). Feyerabend's adduces many arguments to support this principle. The earliest and most technical is Feyerabend's contention that a specific class of observations may become actual falsifiers of an established theory only if they are part of a concurrent theory. In such cases, only the development of a concurrent theory can produce instances that may falsify the established theory. This means that the empirical content of a given theory can be augmented by developing and improving alternative theories. Feyerabend elaborated on this possibility by discussing e.g., the historical case of Brownian motion in physics. He contented that Brownian motion, while having been already a well-known phenomenon, became supporting evidence for statistical thermodynamics and a refutation of classical thermodynamics only with the advent of kinetic theory.

Feyerabend introduced a further principle of theoretical pluralism: "The principle of proliferation not only recommends invention of new alternatives, it also *prevents the elimination of older theories which have been refuted*" (Feyerabend, 1965: pp. 224–225). The latter he called the *principle of tenacity*. From early on Feyerabend's interpreted falsificationism to extend to falsifying instances as well; and "testing a falsifying instance in all possible ways is just the same as trying out all possibilities of making it compatible with the proposed theory" (Hoyningen-Huene, 2006: p. 627). A fact inconsistent with the theory under scrutiny is not *ipso facto* a falsifying instance; it ought to be challenged by the very theory it is inconsistent with and it has to earn the right to become an actual falsifier. Yet "once a falsifying instance has been produced the theory falsified will have to go"

(Hoyningen-Huene, 2006: p. 627). The principle of tenacity goes further and invites to consider refuted theories as part of the realm of relevant theories: "The principle of tenacity is reasonable because theories are capable of development, because they can be improved, and because they may eventually be able to accommodate the very same difficulties which in their original form they were quite incapable of explaining" (Feyerabend, 1970a: p. 204).

Realism

Feyerabend has produced several arguments for a realistic interpretation of scientific theories. His realist position has puzzled many contemporary commentators, since his conception of realism does not resemble today's scientific realism; indeed, it denies central features of it. The disagreement in the early realism debate concerned almost exclusively the question of whether scientific theories should be taken at face value as truth-apt descriptions of the world. Proponents of a (strict or relaxed) verificationist approach would reject it ('positivism'), while empiricists repudiating verificationism would accept in various ways the claim that statements about theoretical entities could be truth-apt ('realism'). Thus the discussion was about semantic realism and both sides mostly agreed that epistemological and ontological considerations in support of realism – unlike today – were metaphysics to be rejected. From the perspective of today's scientific realism one can appreciate the latter position at best as a 'realist faction' in a principled empiricist framework. At that time, however, proponents in this tradition would self-identify as realists. Feyerabend's self-professed early realism must be positioned in this early context and interpreted in light of this early philosophical terminology.

In Feyerabend's realism his theoretical pluralism, critique of sense-data epistemology, the methodological nature of philosophy, come together. The earliest negative argument for Feyerabend's realism is that the alternative, namely positivism, is an untenable groundwork for empiricism. He simply shows that verificationist accounts of experience all rely on untenable sense-data epistemology (or equivalent accounts) thus blocking the main motivation to deny the meaningfulness of theoretical concepts. Theoretical concepts may be truth-apt after all. His positive argument for realism draws on his methodological understanding of the realism debate. Feyerabend's main arguments are pragmatic in character: "Is it useful to believe that scientific theories are true?" In this framework, the first premise of his argument for realism is that a realistic interpretation of scientific theories is conducive to maximize their testability (while instrumentalist interpretations reduce their testability). Since testability is a fundamental epistemic goal of the scientific enterprise (second premise), it follows that scientific theories ought to be interpreted realistically.

Feyerabend contends that allowing for a putative truth-value of statements about theoretical entities expands the class of potential falsifiers of the theory containing said statement, thus increasing its testability: simply put, if we take statements about theoretical entities to be truth-apt, those statements may turn out to be false. Under an instrumentalist interpretation, by contrast, the theory's statements about unobservables are not truth-apt and, therefore, not capable of being refuted. And this is, indeed, Feyerabend's contention: under a realistic interpretation a theory's empirical content increases, while under an instrumentalistic one it decreases. (As new observations alone cannot refute unobservables, this demand crucially extends to the proliferation principle: only realistically interpreted alternative theories may posit theoretical entities contradicting the theory under scrutiny.)

Feyerabend's disavowal of this general realism advanced throughout the 1960s with his increasing skepticism toward general methodological rules. His studies made him aware of cases in which scientists would contravene general methodological rules with good scientific reasons, as dictated by the specific situation of their research. While Feyerabend would still take exceptions on general methodological grounds, he came to appreciate instances of local instrumentalism. A scientist by training, Feyerabend appreciated how such instances made him doubt the viability of his previous conclusion that scientific theories ought to be interpreted in a certain way no matter what the particular research situation is. Abandoning this general realism, he came to appreciate both locally justified interpretations and methodological rules tied to specific theories and research situations.

In the 1980s and early 1990s, Feyerabend's position regarding realism has been variously interpreted, ranging from a strong idealism cast in social-constructionist terms (Preston, 1998), to 'process-realism' (Farrell, 2001), to a sort of neoplatonism (Kidd, 2012). Having renounced his earlier scientism, i.e., the view that science gives us the only, or, at least, better means to attain knowledge about the world, Feyerabend extended his pluralism beyond science. For a time Feyerabend seems to have entertained the idea of an ontological disunity: different ways of knowing the world may hint at different realities being discovered. This definitely changed when he later introduced a strong metaphysical view about the unity of reality in the form of a 'Being' or simply 'Nature,' as he variously called it: The different realities that are discovered through radically diverse ways of knowing the world are, in fact, different ways in which the one ineffable Nature reacts to these discovery attempts. Further, Feyerabend questioned the assumption of a principled separability between the act of discovery and resulting entities or processes being discovered, arguing that the entities or processes being discovered may not exist independently of the circumstances of their discovery (Feyerabend, 1999).

Incommensurability

The term 'incommensurable' ('without a common measure') was first used in 1962 by both Paul Feyerabend and Thomas Kuhn to describe a specific relation – or lack thereof – between pairs of universal theories (Feyerabend) or paradigms (Kuhn) occurring in the history of science. Though Feyerabend's and Kuhn's accounts share some features and are directed against earlier accounts of scientific progress in philosophy of science, they were developed independently and are not easily reconcilable (Hoyningen-Huene, 2004).

Feyerabend's notion of incommensurability can be divided into different stages, starting from a logico-linguistic conception in the 1950s and ending with a hermeneutic-ontological conception in the 1990s. The possibility of incommensurability appears first as a counterfactual thought experiment in his dissertation (1951), but he only started to think about it as an actual phenomenon a few years later, finally leading to the best known and most discussed version of the incommensurability thesis of 1962.

The best known version of the incommensurability thesis states that mutually logically disjoint pairs of scientific theories present themselves as an actual phenomenon in the history of science and that this phenomenon is necessary for the ongoing development of science. The thesis was directed against accounts of intertheoretic reduction and explanation put forward by Logical Empiricism. It was argued that famous transitions in physics, from Galileo's law of free fall to Newtonian mechanics, and from the latter to Einstein's special theory of relativity, would adhere to this schema. The incommensurability thesis maintains that this account fails in exactly these paradigmatic situations. The main argument presented by Feyerabend in support of his refutation contended that the reduction relation presupposes a principle of meaning invariance across consecutive theories, such that the meaning of central theoretical terms in the former theory, as well as the meaning of observational terms, would be retained in the newer theory. This principle, however, does not obtain when considering pairs of realistically interpreted universal theories, because the meaning of central theoretical terms and the meaning of at least some observational term of the older theory is not retained by the successive theory. Instead of reducing or explaining the older theory, the newer theory replaces it. While Feyerabend conceded the later theory would often retain the previous theory as a limiting case, the former would just retain a numerical surrogate of the latter, not its conceptual apparatus. Still, Feyerabend maintained that the proliferation of incommensurable theories is essential for the progress of science as they instantiate the strongest case of alternative theories that may mutually contribute to the increase of their respective empirical content, aiding theoretical pluralism.

The logico-linguistic version of the incommensurability thesis sparked a strong debate that targeted the tenability of the very concept of incommensurability as well as its application to specific cases in the history of science. Among the objections were the rivalry objection (How can two theories be both logically disjoint and yet contradict each other?) and the relevance objection (How can two incommensurable theories be said to apply to the same empirical domain?). Feyerabend replied to these objections throughout the 1960s, trying to correct what were to become long-lasting misreadings like the contention that incommensurability implies incomparability between scientific theories, a misreading far from Feyerabend's view. In fact he maintained that incommensurable alternatives, while being problematic for formal philosophical accounts of scientific development, give a variety and *better* means of comparing the merits of theories. However, under pressure and becoming increasingly dissatisfied with his own precisations, he finally gave up trying to devise a precise account, declaring to be unable to formulate such an account.

Nevertheless, he did not gave up the concept itself, maintaining that incommensurability has an important explanatory and descriptive role to play in the history of ideas and cultural practices. Starting with the introduction of epistemological anarchism, he recast incommensurability as a historical–hermeneutical thesis to be shown – rather than proved – by means of historical–anthropological analysis in subsequent frameworks of thought, in changes of perception frameworks as well as in styles in the figurative arts and in poetry.

Epistemological Anarchism

Feyerabend's epistemological anarchism (or Dadaism) was first advanced in 1970. Its central thesis is that methodological rules have only limited validity and application in science or, more generally, that science is governed by a liberal practice in which methodological rules are, at best, used as rules of thumb. This thesis is explicitly cast both in a descriptive and normative form: For one, historically, "[w]e find […] that there is not a single rule, however plausible, and however firmly grounded in epistemology, that is not violated at some time or other" (Feyerabend, 1993: p. 14). Second, "[t]his liberal practice […] is not just a fact of the history of science. It is not merely a manifestation of human inconstancy and ignorance. It is reasonable and absolutely necessary for the growth of knowledge" (Feyerabend, 1993: p. 14). A third, often ignored, but not less important motive is the ethical grounding of his proposal: "Such an anarchistic epistemology […] is not only a better means for improving knowledge, or of understanding history. It is also more appropriate for a free man to use than are its rigorous and 'scientific' alternatives" (Feyerabend, 1970b: p. 21).

Feyerabend supports his thesis with a detailed study of the Scientific Revolution and the rise of Copernicanism in the sixteenth and seventeenth century. The study purports to show that Galilei's defense of the heliocentric hypothesis violated basic tenets of modern scientific methodology and that it followed through exactly because of this violation. Feyerabend also purports to show that the opposing party, personified by Cardinal Bellarmine, argued against the heliocentric hypothesis on the basis of sound empiricist tenets. Concurrently, and even more controversially, the Church is interpreted as recommending the evaluation of the view of experts in the light of social and ethical values, whereas Galileo is seen as advocating *ante litteram* the acceptance of a privileged role of experts in society. The conclusion Feyerabend draws is twofold: Galilei could not have successfully defended the heliocentric hypothesis at the time without violating basic tenets of empiricism; and the opposition to Galilei, the Roman Catholic Church in particular, had good scientific and ethical reasons on their side to reject Galilei's scientific venture. Feyerabend's choice to use Galilei as a case study is crucial for his argument. If Galilei, the epitome of the modern scientist fighting against obscurantism, did not act according to the standard scientific methodology, who could possibly have? Because the Scientific Revolution has been viewed as the paradigmatic example of scientific progress, a revisionist historical–philosophical account, if correct, casts doubt on the usefulness of conventional accounts of scientific progress. In this way Feyerabend wants to generalize from a single but paradigmatic case to the scientific enterprise as a whole.

Because of its unabashed provocative claims, several charges have been leveled against Feyerabend's theses. Some have been unanimously identified as relying on misconceptions or misunderstandings of his work; other have been substantiated. For one, Feyerabend's conclusion has been read as against Galilei's scientific achievement or, alternatively, against the notion that Galilei's defense of heliocentrism was justified. Quite the contrary, Feyerabend's goal is to uphold Galilei's scientific achievement and to show the inadequacy of standard accounts of scientific rationality. Second, Feyerabend's intention has been interpreted as proposing a new anarchistic methodology to replace the empiricist one. This is arguably not the case: "My intention is not to replace one set of general rules by another such set: my intention is, rather, to convince the reader that *all methodologies, even the most obvious ones, have their limits*. The best way to show this is to demonstrate the limits and even the irrationality of some rules which she, or he, is likely to regard as basic" (Feyerabend, 1970b: p. 21).

The latter misconception arose because Feyerabend did not just show cases of basic empiricist rules being violated, but he affirmatively formulated and defended the use of increasingly heterodox methodological rules in science. Starting with the proliferation principle, later complemented by the tenacity principle, Feyerabend liberalized methodology, leading to the formulation of counterinduction as an additional rule of thumb stating that it may be useful to introduce hypotheses that are inconsistent not just with established *theories* – as the proliferation principle suggests – but with well-established *facts*. But counterinduction is not meant to be a new methodology. Indeed, Feyerabend's analysis of Galilei's scientific practice purports to show that Galilei proceeded counterinductively on several occasions. And it is not introduced to supplant existing methodological rules: proceeding counterinductively is suggested "*in addition* to proceeding inductively" (Feyerabend, 1970b: p. 26).

The catch phrase associated with epistemological anarchism is 'anything goes.' Though it appears only once in the book, it has been used ever since as purportedly expressing the main principle of Feyerabend's epistemological anarchism. This is arguably mistaken. Feyerabend introduces 'anything goes' as a rhetorical device, distilling the only principle an advocate of methodological monism could possibly uphold in the face of the pluralism to be found in science and its history. But his point is to show that such a principle would be empty, and thus implies to abandon monism and an invitation to accept pluralism – 'many things go' – not to adopt an empty methodological rule.

More substantive objections have been made to Feyerabend's historical interpretation of Galilei's undertaking and his argument with the Church. Since Feyerabend did not produce new historical material, these objections pertained Feyerabend's handling of the available historical material and the cogency of the conclusions he drew from it (Machamer, 1973; McMullin, 1970). Whether this invalidates Feyerabend pluralist conclusion as well is open to debate.

While epistemological anarchism has been viewed as a radical departure from his earlier views, the actual change is rather subtle, at least when compared to the strong consequences Feyerabend drew from it. The increasing skepticism toward general methodological rules was prompted by the raising awareness that philosophical issues in the sciences may at times not be resolved by appealing to general methodological rules, but be forced upon by the circumstances of specific research contexts. Nevertheless, methodological rules do not become useless in Feyerabend's analysis, they merely loose generic means of justification and become subject to context-dependent justification. Feyerabend's methodological pluralism embraces the different contexts of scientific research, analyzing which epistemic values were adopted and why they were adopted in given contexts.

Philosophy of Nature and the Rise of Rationalism

Against Method's main claim that the rationality of science is incompatible with its 'rational reconstruction' leaves open at least two options. The failure of standard accounts of rationality to account for science and its progress "means either that there cannot be any discoveries unless one leaves the house of reason, or that the house of reason is very different from what philosophers and other idea-mongers make it out to be" (Feyerabend, 2011: p. 112). The success of *Against Method* and its vitriolic rhetoric lent credibility to the idea that Feyerabend went with the first option, instead of hinting at his true intentions of giving a detailed account in which way(s) 'the house of reason' might differ from formal philosophical accounts, a project which was published only posthumously (Feyerabend, 2009).

In his final writings, he relented the acrimony of his earlier works, giving way to an unsystematic resumption of his project to describe 'the rise of rationalism' and to give an alternative account of scientific and nonscientific rationality and the relationship between the two (Feyerabend, 2011, 1999). In these works, he invites the reader to rethink the relationship between the empirical and theoretical dimensions of human agency, science being one such activity among many. While an abstract notion of knowledge, namely theoretical knowledge, is necessary to science, it is not sufficient, as science only succeeds embedded in specific practices. Indeed, his claim is that the theoretical dimension is but a kind of particular practice. Science is, therefore, best understood as a theoretical and practical craft.

Democratic Relativism

Feyerabend's strong ethical commitment and his considerations about the close relationship between morality and knowledge, between ethics and epistemology, are documented long before his more controversial pronouncements in *Science in a Free Society* (see Feyerabend, 1961). Yet they turned into more global considerations about science and society only with the advent of *Against Method*, borrowing from political philosopher John Stuart Mill and other thinkers. In particular, he applied Mill's insights in *On Liberty* (1859) to extend theoretical pluralism beyond science to other forms of knowledge, turning theoretical pluralism into global considerations about the necessity of a plurality of points of view and of traditions and the required conditions under which these points of view could develop and thrive (Feyerabend, 1987, 1978).

Feyerabend is best known for his positive appraisal of several social and philosophical theses which he subsumed

under the heading of relativism. 'Relativism' has long been used as a negative epithet in philosophy, rarely as a philosopher's positive self-description. (For a recent philosophical reappraisal of Feyerabend's relativism see Kusch, forthcoming.) Not so in fields like anthropology and sociology of knowledge, where relativism has a long standing pedigree as a central methodological premise. Likewise, his target audience is clearly not the philosophical community anymore, but a more general learned audience.

At the core of Feyerabend's relativism lies the ideal of a free society (a terminological choice polemically opposed to Karl Popper's open society) in which all traditions ought to enjoy equal rights and opportunities. (This he calls 'democratic' or 'political' relativism.) Feyerabend's central move is twofold: To conceptualize science as one tradition among many and to renounce even a moderate form of scientism, the view that science gives us better means to attain knowledge than other traditions, which lies at the basis of the scientific worldview. Yet this does not imply that all traditions' beliefs are equally true or false (a view which Feyerabend calls 'philosophical relativism' and rejects). His main target is the predominant *political* and *social* role of science within today's societies. While science is the only one among many traditions, the scientific worldview stipulates that science mediates and is introduced as an arbiter into the discourse among traditions, i.e., has a privileged position in collective social–political decision-making process. According to democratic relativism, this privileged position is incompatible with the flourishing of a plurality of traditions. Also, science is given the power to stipulate the very rules that govern the interchange between traditions. To exemplify his proposal of a free society and the role of experts therein, Feyerabend draws an analogy to courts of law in which citizens are judged by a jury of peers (Feyerabend, 1978: p. 97). While experts may be called to testify, they do not necessarily have an exceptional standing and are one factor among many leading to the final verdict that is deliberated and agreed upon by a group of peers. In a similar way, a free society urges that citizens should have the final say in social–political decision-making.

Fiducial and Structural Statistical Inference

Donald AS Fraser, University of Toronto, Toronto, ON, Canada

© 2015 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 8, pp. 5616–5620, © 2001, Elsevier Ltd., with an updated Bibliography section supplied by the Editor.

Abstract

Fiducial inference provides probabilities for parameters on the basis of a statistical model and data; structural inference also provides such probabilities but requires a specialized transformation structure in the model. A comparison of the fiducial and structural methodologies with default Bayesian analysis is given and shows that both can be viewed as specializations of the Bayesian. Examples are given and comparisons made.

Fiducial inference is a statistical approach to interval estimation first advocated by R. A. Fisher as an alternative to the then dominant method of inverse probability, i.e., using Bayes' Theorem. Considerable effort has gone into formalizing Fisher's notions using such concepts as statistical invariance and pivotal quantities. This article describes elements of the fiducial approach and relates them to other currently more widely used statistical approaches to inference. Section A Simple Example introduces some basic inferential ideas via a simple example.

A Simple Example

Consider a variable y that is directly available or has arisen by some preliminary reduction process and suppose that y measures θ in an unbiased manner and has error that is normal with known variance σ_0^2. Then we can say for example that $P(y \leq \theta + 1.64\sigma_0;\ \theta) = 95\ \%$.

Parenthetically, we note that the preliminary reduction could have occurred as part of the underlying investigation or as part of some subsequent simplification of the statistical model by one of the common statistical reduction methods, sufficiency or conditionality. If the reduction is to a sufficient statistic, then the conditional distribution describing possible antecedent data has no dependence on the parameter and the model for the sufficient statistic is used in place of the original model. If the reduction is by conditionality then there is typically an ancillary variable with a distribution free of the parameter and the given model for the possible original data is replaced by the conditional model given the ancillary (supportive) variable; *see also* Statistical Sufficiency.

With a data value y^0 the fiducial methodology would take the above probability expression and substitute the value y^0 and then treat θ as the variable for the probability statement, thus giving a 95% fiducial probability statement $P(\theta \geq y^0 - 1.64\sigma_0;\ y^0) = 95\%$. The structural approach would consider the normal $(0;\ \sigma_0^2)$ distribution for the error $e = y - \theta$ and might record for example the probability $P(e \leq 1.64\sigma_0) = 95\%$; then with data value y^0 the probability statement would be applied to the error $e = y^0 - \theta$ giving the structural probability $P(y^0 - \theta \leq 1.64\sigma_0;\ y^0) = 95\%$ or equivalently $P(\theta \geq y^0 - 1.64\sigma_0;\ y^0) = 95\%$. In a somewhat related manner the Bayesian methodology might use a uniform prior $cd\theta$ and obtain a posterior distribution for θ that would have $P(\theta \geq y^0 - 1.64\sigma_0;\ y^0) = 95\%$. For this simple example the three methods give the same result at the 95 percent level and also at other levels, thus saying essentially that with data value y^0 the probability distribution describing the unknown θ is normal $(y^0; \sigma_0^2)$.

With more complicated models the results from the three methodologies can differ and philosophical arguments concerning substance and relative merits arise. However, for one straightforward generalization the methods remain in agreement: the normal distribution can be replaced by some alternative distribution form; this is discussed in some detail in Sect. 2.

Fiducial Probability

Fisher (1922, 1925; see also Fisher, Ronald A. (1890–1962)) had already introduced most of the fundamental concepts of statistical theory, such as sufficiency, likelihood, efficiency, exhaustiveness (minimal sufficiency), when he chose (Fisher, 1930) to address directly the aspiration mentioned above. He took Laplace and Gauss to task for 'fall(ing) into error on a question of prime theoretical importance' by adopting the Bayesian approach that 'Bayes (had) tentatively wished to postulate in a special case' and which was published posthumously (Bayes, ibid). Be then proposed in a restricted context the fiducial method, as discussed.

Neyman and Pearson (1933) then gave a mathematical formulation of fiducial probability that became known as confidence intervals. Fisher (1956) however treated Neyman and Pearson's formulation as a 'misconception having some troubling consequences …'; logical and philosophical arguments between the two sides were intense for many years. In particular the slight to Laplace and Gauss may well have affected the views of the more mathematical participants.

Fisher (1930) entitled his paper 'Inverse Probability' and examined a statistic $t(y)$ whose distribution depended on a single parameter θ. Let $P = F(t;\theta)$ be the distribution function of t, and let P itself be what we might now call a p-value for assessing θ; of course in the usual continuous case P has the uniform distribution on (0, 1). 'If now we give P any particular

value such as 0.95, we have … the perfectly objective fact that in 5% of samples' t 'will exceed the 95% value corresponding to the actual value of θ ….' Then to 'any value of' t 'there will moreover be usually a particular value of θ to which it bears this relationship; we may call this the 'fiducial 5% value of θ' corresponding to' the given t. This led to Neyman and Pearson's (ibid) confidence methodology but Fisher treated this as a misconception and he followed different directions and interpretations for the fiducial methodology; for a view on related approaches see Estimation: Point and Interval. For this present simple case with scalar t and scalar θ, there seems little difference between the fiducial and the confidence approaches and interpretations.

This discussion effectively ascribes a distribution to θ based on an observed t; this is called the fiducial distribution for θ. Just as the density of t for given θ is obtained as $(\partial/\partial t)$ $F(t;\ \theta)$ so also the fiducial density is obtained as $(-\partial/\partial\theta)$ $F(t;\ \theta)$; the negative sign is inconsequential and is merely the result of $F(t;\ \theta)$ being examined typically for the case that is increasing with θ. The fiducial distribution for cases like the present can also be called the confidence distribution, which recently has a variety of uses in statistical inference. This alternative name emphasizes its more conventional role and attempts to avoid the inappropriate stigma that surrounds the fiducial concept.

For the fiducial approach in more general contexts, Fisher (1935) recommended a maximum reduction to a statistic $t(y)$ by the use of sufficiency. For example, with a sample $y_1,\ldots,y_n$ from the normal $(\mu;\sigma_0^2)$ distribution, the reduction would be to $t(y) = (\bar{y}, s_2^y)$. The methodology then suggests the use of a pivotal quantity $p = p(t;\ \theta)$ with a fixed distribution and a one-one relationship between any two of p, t, θ; recall more generally that a pivotal quantity is a function of the variable and parameter that provides a measure of departure of variable value from parameter value, and has a fixed distribution which allows an assessment of an observed departure. Thus for the example a natural pivotal is

$$\left\{z = \frac{\bar{y}-\mu}{\sigma/\sqrt{n}}, \chi^2_{n-1} = \frac{(n-1)s_Y^2}{\sigma^2}\right\}$$

which has independent components, normal (0, 1) and chi-square with $n-1$ degrees of freedom. Fisher (1956, p. 172), however, rather deviously rejected this as a legitimate part of the fiducial methodology, but he was somewhat less explicit about what would be legitimate. This pivotal reduction procedure is now however a rather familiar component of standard inference theory and in particular of confidence theory.

The final step is to invert the pivotal quantity, that is, to insert the observed values for the variables and then transform the distribution of the pivotal quantity to the parameter. For the example this gives

$$\mu = \bar{y} - \left\{z/(n-1)^{-1/2}\chi_{n-1}\right\}s_Y/\sqrt{n}$$
$$\sigma^2 = (n-1)s_Y^{22}/\chi^2_{n-1}$$

where the $\bar{y}, s_Y^2$ have their observed values. We can then write

$$\mu = \bar{y} - ts_Y/\sqrt{n}$$

where t is Student with $n-1$ degrees of freedom. This fiducial calculation closely parallels that for the confidence approach, except that the limits here are calculated from the Student distribution for μ rather than from the Student distribution of the pivotal t. In quite wide generality fiducial regions can correspond to confidence regions; it is just a matter of whether the limits are calculated before or after the data are observed, a non-issue from the Bayesian viewpoint.

There are however cases where routinely obtained confidence and fiducial regions can differ. For example, consider a sample $(y_{11},y_{12}),\ldots,(y_{n1},y_{n2})$ from a bivariate normal distribution with means μ_1, μ_2, variances σ_1^2, σ_2^2, and correlation ρ, and suppose primary interest centers on the regression coefficient $\beta = p\sigma_2/\sigma_1$ of the second variable on the first variable. Standard regression analysis of the second variable on the first variable can produce an interval that differs from that obtained from the joint fiducial or structural distribution for all the parameters by integrating out the unwanted parameters; see for example, Fraser (1979, pp. 189, 204, 280, and 293). Also there are other familiar cases where fiducial, structural and Bayesian methods can differ; see for example, the Behrens-Fisher and the Fieller-Creasy problems, and for some discussion see Wallace (1980).

Now suppose we generalize and examine a sample $y_1,\ldots,y_n$ from some distribution with location μ and scale σ. For example the basic form $f(z)$ of the distribution might be, say, the longer-tailed logistic, or the Student with 6 degrees of freedom often cited as a realistic error pattern. The distribution for the underlying errors is then $f(z_1)\ldots f(z_n)$ and for the sample is

$$\sigma^{-n}\prod f\{\sigma^{-1}(y_i-\mu)\}$$

With a typical general error shape we do not have a simple minimal sufficient statistic as with the normal error pattern above. Fisher (1934) then recommended conditioning on an ancillary statistic and suggested the statistic

$$d_1 = \frac{y_1-\hat{\mu}}{\hat{\sigma}}, \ldots, d_n = \frac{y_n-\hat{\mu}}{\hat{\sigma}}$$

called the configuration statistic, whose coordinates are standardized residuals, standardized here with respect to maximum likelihood values. The conditional distribution of $(\hat{\mu}, \hat{\sigma})$ is fairly easily expressed in terms of likelihood. Let

$$L^0(\mu,\sigma) = c\sigma^{-n}\prod f\{\sigma^{-1}(y_i^0-\mu)\}$$

be the observed likelihood function from data $(y_1^0,\ldots,y_n^0)$, and $(\hat{\mu}^0, \hat{\sigma}^0)$ be the observed maximum likelihood values. Then the conditional distribution given the observed configuration statistic $(d_1^0,\ldots,d_n^0)$ is

$$g(\hat{\mu},\hat{\sigma}|d^0;\mu,\sigma)\frac{d\hat{\mu}d\hat{\sigma}}{\hat{\sigma}^2} = cL^0(\hat{\mu}^0 + (\mu-\hat{\mu})\hat{\sigma}^0/\hat{\sigma}, \sigma\hat{\sigma}^0/\hat{\sigma})\frac{d\hat{\mu}d\hat{\sigma}}{\hat{\sigma}^2}$$

which can be used to give confidence intervals; also a straightforward fiducial argument following that for the normal case gives

$$L^0(\mu,\sigma)\frac{d\mu d\sigma}{\sigma}$$

for the fiducial distribution. If f is replaced by the standard normal we get the result discussed earlier and we get it without

any reference to sufficiency. This with some other results suggests (Fraser and Reid, 2000) that the primary concept sufficiency can be replaced quite widely by appropriate conditioning, and with a major gain in generality of viewpoint.

Fisher (1935) did not use maximum likelihood notation for this location scale model. The notation here adapts to more general contexts (Fraser, 1968; 1979) but needs to be modified if the error distribution involves a shape parameter which would then make the maximum likelihood estimates parameter-dependent.

For more general problems the fiducial can have non-uniqueness difficulties, and these tend to arise from the choice of what pivotal to use. For example with the bivariate normal discussed, different pivotals can produce different fiducial distributions (Fisher, 1956, p. 172, where he elusively denigrates the pivotal approach).

There are also issues connected with finding a marginal fiducial for a component parameter. For a general discussion of marginalization paradoxes connected with methodologies concerning distributions for parameters, including the Bayesian methodology, see David et al. (1973).

For a mathematical analysis that avoids some of the difficulties with the fiducial methodology, see the transformation group framework in Fraser (1961a,b); this mathematical analysis led to the development of the structural approach described below. The marginalization issues still remain, however, and this is related to the common assessment technique of examining a procedure with many repetitions from the same distribution with fixed parameter value. Alternatives to this are suggested in Fraser and Reid (2000).

Structural Probability

In many applied problems it is possible to ascribe an underlying error distribution to the model. For example with measurements that are normal with unknown error scaling we might write

$$y_i = \mu + \sigma z_i \quad i = 1, \ldots, n$$

where the $z_1,\ldots,z_n$, are independent standard normal variables. If we then examine (Fraser, 1966) these expressions with observed data we can note rather easily that many characteristics of the underlying realized errors can be numerically evaluated. Specifically, let

$$d_1 = \frac{y_1 - \bar{y}}{s_Y}, \ldots, d_n = \frac{y_n - \bar{y}}{s_Y}$$

be standardized residuals; then the observed $y_1,\ldots,y_n$ and the underlying realized $(z_1,\ldots,z_n)$ have the same standardized residuals. In fact, $n-2$ characteristics as presented by the residuals are available concerning the underlying errors. Most theory concerning applications of probability would then say the analysis should be conditional on these observed characteristics, that is, on what you know concerning the realized error (Fraser, 1976, Chap. 4, pp. 161–2 and Chap. 11, pp. 456–66). This for quite general problems automatically gives the conditioning used by Fisher and avoids the need to invoke a conditioning principle and seek an ancillary such as the configuration statistic.

This present type of analysis carries through equally (Fraser, 1966) if the normal distribution is replaced by some other error pattern. The conditional error distribution can be viewed from an invariance argument as being valid after the full data are observed. This distribution then gives the structural distribution for μ and σ. The mechanics follow closely what is presented for the fiducial case and the resulting structural distribution agrees with the fiducial distribution, $L^0(\mu,\sigma)d\mu d\sigma/\sigma$. The difference here is that a rather strict invariance structure is assumed as part of the argument. This is summarized in general notation.

The structural approach is possible in cases where the underlying error can be directly modeled and the observed response is obtained as some transformation of this. Let Z designate a general error variable with known density $f(Z)$ on say R^n. Let Y designate the response as obtained by a transformation or reexpression θ in some space Ω. Then we have

$$Y = \theta Z, f(Z)dZ,$$

For the invariance we assume that a transformation θ carries R^n into R^n and that the collection Ω of such transformations is closed under composition and inversion. Also for details here we assume that the transformations are smooth and at most one transformation carries a point Z into a point Y. For some general background on transformations and invariance, *see* Causal Inference and Statistical Fallacies.

If we consider all the transformation Ω and apply them to a data point Y^0 we obtain a set ΩY^0 of images, of possible antecedent error values. If Z^0 is the unknown realization of error that produced Y^0 then we have $\Omega Z^0 = \Omega Y^0$ or equivalently we have that Z^0 lies in the set ΩY_0. This means that a probability assessment should be made conditional on the observed set ΩY^0. Let $D(Z)$ be a reference point in the set ΩZ and let $[Z]$ in Ω be the transformation in Ω that carries $D(Z)$ to Z. Then we have that the model $Y = \theta Z$ with data Y^0 can be rewritten as

$$[Y] = \theta[Z], \quad D(Y) = D^0,$$

giving the conditioning $D(Y) = D(Y) = D^0$ that appears as an observed ancillary in the fiducial framework. The conditional distribution of $[Z]$ given $D(Z) = D^0$ then describes the reduced model $[Y] = \theta[Z]$ with data $[Y^0]$. The structural distribution of θ is then given as $\theta = [Y^0][Z]^{-1}$ using the conditional distribution $[Z]$ just described.

In most contexts the support measure dZ can be replaced by an invariant measure $dM(Z)$

$$dM(Z) = \frac{dZ}{J(Z)}$$

where $J(Z)$ is an appropriate Jacobian (Fraser, 1979). Expressions are simpler if we use density $f(Z)$ with respect to the measure $dM(Z) : \bar{f}(Z) = f(Z)J(Z)$.

The distributions of $[Y]$ and $[Z]$ conditional on $D(Y) = D(Z) = D^0$ are

$$c\bar{f}(\theta^{-1}[Y]D^0)d\mu[Y], \quad c\bar{f}([Z]D^0)d\mu[Z]$$

where $d\mu[Z]$ is the corresponding invariant measure on the group Ω. The inverted distribution, called the structural distribution for θ, is

$$c\bar{f}(\theta^{-1}[Y^0]D^0)d\nu(\theta) = cL^0(\theta)d\nu(\theta)$$

using the right invariant measure ν on the group Ω. In the Bayesian context the typically preferred noninformative prior is the right invariant measure $d\nu(\theta)$. Thus the structural distribution coincides with this preferred Bayesian posterior.

This group type model covers a wide range of regression multivariate and spherical distribution models but not in the simplified notation used here; for further details see Fraser (1968, 1979).

Recent likelihood asymptotics has been able to obtain many aspects of these results in a general asymptotic context; see Fraser et al., (1999a,b).

Comment

Fiducial inference led to confidence intervals, with both having evolved from the Bayesian procedures initiated in the eighteenth century. In terms of freedom of usage, we have Bayesian inference as the more liberal. The foundational issues center on validity and interpretation of the probabilities for the parameters. Here the conditions are strictest for the structural and minimal for the Bayesian. In the nice cases they agree; and in the less standard cases they pressure the proponents to clarify their assumptions.

For some recent discussion of confidence and fiducial interconnections plus references see Barnard (1995), with complementing views in Fraser (1996). Also see Fraser and Reid (2000) for a discussion of the interplay with objective Bayesian methods.

Field Experiments

Abstract

Field experiments are experiments in settings with high degrees of naturalism. This article describes different types of field experiments, including randomized field trials, randomized rollout designs, encouragement designs, downstream field experiments, hybrid lab-field experiments, and covert population experiments, and discusses their intellectual background and benefits. It also lists methodological challenges researchers can encounter when conducting field experiments, including failure to treat, selective attrition, spillover, difficulty of replication, and black box causality, and discusses available solutions. Finally, it provides an overview over current and emerging directions in field experimentation and concludes with a brief history of field experiments.

Definitions

Field experiments are experiments in settings with high degrees of naturalism. *Experiments* are studies using some type of random procedure, such as a coin flip or a random number generator, which determines for each participant whether they receive a treatment versus no treatment or a comparison treatment. *Random assignment* in expectation ensures balance on observable and unobservable confounding variables between the treatment groups and thus allows for causal claims about the effect of the treatment on the outcomes of the group. In other words, through random assignment the researcher can causally attribute recorded outcomes to treatments or manipulations. For example, assume that participants are randomly assigned to two different weight loss programs, A and B. If, at the completion of the two programs, the average weight of participants in program A is significantly less than participants in program B according to a standard statistical test of difference in means, the researcher can infer that program A is more effective at causing weight loss compared to program B. In the absence of random assignment, it is possible that people with lower body fat, a higher motivation to lose weight, or another unobservable characteristic disproportionately participated in program A due to the biased choices of participants or the experimenter. These characteristics could explain the difference in weight loss that has nothing to do with the program itself.

In the weight loss example, individuals are the *experimental units* that are randomly assigned to different treatments. Experimental units may be people but can also be other entities, such as communities, households, or school classes. When groups of people, such as groups of friends, rather than individuals, are assigned to a treatment, this is referred to as *clustered random assignment*. *Blocked random assignment* occurs when experimental units are first grouped into blocks according to similarities in any particular observed characteristic, and then randomly assigned to treatment within each block. For example, researchers can first block individuals into six groups defined by previous academic achievement and sociodemographic background, and then randomly assign individuals within each block to an experimental tutoring intervention versus a no-tutoring control. In field experiments, random assignment usually occurs *between subjects*: each participant receives only one of several treatments. For example, researchers may randomly assign a sample of 300 companies to receive one of two resumes that are identical except that one is from a black applicant (treatment 1) and the other from a white applicant (treatment 2). The measured outcome is whether each company contacts the fictional applicant for an interview. In this case, each company only receives one resume, either from a white *or* from a black candidate. An alternative approach is a *within-subjects* design in which experimental units are exposed to multiple treatments. For example, researchers may send comparable resumes from both a white and a black applicant to the same company. An advantage of within-subjects designs is that they generally require smaller samples than between-subjects designs. A disadvantage is that it remains unclear if the outcome was caused by any single treatment or by the sequence of all available treatments. This requires at least a counterbalanced design in which half of the companies are randomly assigned to hear from a black then a white applicant, and the other half hear from a white and then a black applicant.

The term experiment has a precise definition: the term *field* is more open to interpretation. Generally, a field experiment is an experiment in a setting with a high degree of naturalism. Researchers can determine the *naturalism* of an experiment based on the following four considerations (Gerber and Green, 2012): (1) Does the treatment or manipulation in the study resemble the intervention of interest in the world? (2) Do participants in the study resemble the actors who usually encounter these interventions? (3) Does the context within which participants receive the treatment resemble the context of interest or is it, for example, more obtrusive? and (4) Does the outcome measure resembles the actual outcome of theoretical or practical interest? For example, a field experiment would test a real door-to-door campaign rather than a simulated doorstep conversation, would target citizens who are eligible to vote rather than a convenience sample of students in a class, would locate the door-to-door campaign in a neighborhood where it is meant to take place instead of a college campus, and would assess actual voting behavior directly rather than asking participants about their intention to vote in a survey.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10542-2

Conventional laboratory experiments with a nonnaturalistic intervention but with a nonstandard subject pool (i.e., members of the community who are the real-world targets of the simulated intervention) are sometimes called *artifactual field experiments*. An example for an artifactual field experiment recruited small business man of Turkish versus Belgium origin as research participants, and instructed them to play behavioral economics trust games (Bouckaert and Dhaene, 2004).

Experiments with a nonstandard subject pool and a naturalistic treatment or manipulation are sometimes called *framed field experiments*. In an example for this type of experiment, Love et al. (2005) randomly assigned low-income pregnant women and families with infants and toddlers to the 'early head start' child development program or to a control group. Early head start is an existing program that serves precisely these communities. Researchers gathered the outcomes of interest, child development, and parenting, mostly through interviews and test batteries, making participants aware of the research activities.

Quasi-experiments (see Shadish et al., 2002) where at least one treatment is not randomly assigned, as well as *natural experiments* (see Dunning, 2012) where random assignment occurs through an exogenous force that is not under the control of the researcher are distinct from field experiments and will not be covered in this encyclopedic article.

Intellectual Background

A considerable number of scholars across the social sciences advocate for field experiments. Which benefits they emphasize often depends on their disciplinary background. Pro-field experiment arguments made by social psychologists (Cialdini, 2009; Paluck and Cialdini, 2014) highlight the advantages of field experiments relative to laboratory experiments. In contrast, political scientists (Gerber et al., 2004; Gerber and Green, 2012) and sociologists (Pager, 2007) often focus on the advantages of field experiments relative to observational research. Economists stress both advantages when making the case for field experiments (Banerjee and Duflo, 2009).

The most frequent argument for field versus laboratory experiments is that *field experiments often have greater external validity than laboratory experiments*. Because treatments, participants, settings, and outcomes closely resemble those as they naturally occur in the world, lessons gained through field experiments may be more relevant to the social and political questions the experiment was designed to test.

In contrast to observational studies, field experiments can establish *causality* and provide *unbiased treatment effects* even in the absence of strong priors. Going beyond most laboratory experiments, field experiments can also *test the robustness of causal relations*. Because in their everyday realities people often encounter a myriad of stimuli and distractions, it is important to test the robustness of causal relations in such messy settings. For example, Gerber et al. (2008) found that high-social-pressure mailings that were randomly assigned to a subset of households increase voter turnout. These findings are remarkable considering how many steps lie in between receiving mail and casting one's ballot in a voting booth. In addition to providing useful knowledge about increasing voter turnout, the findings from this study powerfully demonstrate the strength and therefore theoretical importance of social pressure in civic behavior.

Although field experiments are often equated with program evaluation, the social pressure and voting study is one of many demonstrations that this method can be used to *advance scientific theory*. Convention in experimental social science had often assigned the role of advancing basic theoretical science to laboratory experiments, which were presumed to be free of confounds and unnecessary 'noise' or error variance. Field experiments, however, can produce highly accurate treatment effect estimates free of common laboratory artifacts such as experimenter bias and participant reactivity to the perceived demands of the experimental situation or instructions (see Adams and Stocks, 2008). For example, members of a dominant racial group often carefully monitor their behavior in laboratory experiments so as not to appear 'racist.' In field experiments, however, participants are more likely to be unaware of being observed, and real outcomes, for example, purchase transactions, are at stake. For instance, Ditlmann and Lagunes (2014) randomly assigned Latino and Anglo actors to pay for purchases with checks in retail stores, and, found that cashiers more frequently asked Latino actors to present ID when making a check purchase than Anglo actors. The fact that these cashiers were unaware that they were being studied allows us to be more confident that the experiment-captured average rates of discrimination as they occur in everyday life.

Finally, field experiments have a *great potential for innovation and discovery* because researchers do not control all elements of the setting, and thus can make unanticipated discoveries. For example, in a field experiment on the hiring process, Barron et al. (Barron et al., 2011) found that store personnel exhibited greater positivity and engaged in longer interactions when they were randomly assigned to minority applicants who displayed prominently their ethnic identification. This observation contradicts an earlier laboratory finding that high identification leads to negative evaluation of ethnic minorities (Kaiser and Pratt-Hyatt, 2009). The authors speculate that store owners fear discrimination lawsuits if they reject qualified minority candidates whom they suspect to be strong advocates for their groups' rights. The finding thus reveals the power of institutional structures in guiding human behavior – an important discovery for research inside and outside the laboratory.

Current Knowledge

Types of Studies

Field experimentation is a burgeoning field and new types of studies emerge regularly. This encyclopedic article describes some of the most commonly used types of field experiments and provides illustrative examples.

Randomized controlled field trials are the canonical design for field experiments. They compare the effects of two or more interventions or manipulations on outcomes of interest. Individuals from a pool of potential participants are randomly assigned to one or more interventions of interest vis-à-vis

a control or placebo condition. For example, Paluck (2009) randomly assigned Rwandan citizens, clustered in communities, to listen to a radio soap opera program either with prejudice reduction or with health messages. She found that the prejudice-reduction radio program improved norms for intergroup behavior, measured by the way listeners in the prejudice reduction program divided a community resource given to communities in each condition. In another randomized controlled trial, retail customers were offered one of four different pricing programs: 'Pay-what-you-want' or 'fixed-price,' each combined with information that either half of the money or no money would go to charity. Interestingly, participants paid the highest amounts in the program that offered the pay-what-you-want option combined with positive information about charity (Gneezy et al., 2010).

Randomized rollout designs (also called *waiting list designs* or *stepped wedge designs*) are similar to randomized controlled trials. Instead of being assigned to different treatments, all participants receive the same treatment but at randomly assigned varying points in time (time 1 or time 2). Researchers randomly assign half of all experimental units to the treatment at time 1, after which they can compare outcomes, and then researchers give control participants access to the treatment at time 2, after which they can test to see whether this group reacts similarly to the first group. This design is often used when there are ethical or political concerns about withholding the treatment from a portion of the sample. For example, researchers working with a bank in the Philippines offered an attractive savings plan to a randomly assigned selection of customers. Customers in a marketing treatment control condition received access to the plan after a 'product trial period,' i.e., after the research was completed (Ashraf et al., 2006).

Encouragement designs recognize that in some cases, researchers cannot guarantee participants' compliance with their assigned treatment. Instead, researchers randomly assign a subset of potential participants to an 'encouragement' to join the treatment intervention. For example, in the famous New York City school experiment, low-income children were randomly assigned to receive school vouchers, thus giving them the option to switch from public to private school (Peterson et al., 2003).

Downstream field experiments follow up on completed field experiments. They involve the collection of new data from participants in completed field experiments. Once random assignment is successful, researchers can assess the impact of the treatment on any number of outcomes at later points in time. For example, Sondheimer and Green (2010) gathered the voting turnout records of participants who were randomly assigned to participate in programs aimed at increasing high school graduation rates when they were children, to establish the causal effect of education on voting behavior.

Hybrid lab-field experiments are field experiments with elements of artificiality. This type of study is useful for researchers who want to have a high level of control over treatment administration or measurement, while simultaneously reaping some of the field experiment benefits discussed above. For example, Walton and Cohen (2007) brought black and white undergraduates into the laboratory for a brief intervention in which their fears about not belonging at the university were addressed or not. The success of this 'belongingness' intervention was demonstrated by measuring end of year grades that students earned in their college courses, which were higher for black and not white students in the treatment condition.

Covert population experiments use random assignment in a naturalistic setting to measure responses to members of subgroups within that setting that are identifiable by some sociodemographic (e.g., ethnic identity) or ideological (e.g., political affiliation) dimension. Importantly, participants who respond to the measurement paradigm are not aware that they are partaking in an experiment. As a result, covert population experiments often produce more accurate treatment effect estimates than more overt methods, such as self-report questionnaires. *Audit studies*, *correspondence studies*, and the *lost-letter paradigm* are three prominent examples for covert population experiments.

In *audit studies*, individual actors who vary on one or more important demographic dimensions are randomly assigned to engage in the same interpersonal transaction with a sample of people or institutions, for example, purchasing goods at a sample of stores or interviewing for an open position at a sample of companies. Because actors are trained to behave in an identical manner and because the experimental units (the interaction partners) are randomly assigned to one or the other actor, difference in responses is interpreted as evidence for discrimination. For example, in Ayres' (1991) famous 'fair driving' experiment, actors who varied in terms of their ethnicity and gender bargained for a retail car; car salespeople offered white men significantly better prices than white women and blacks.

In *correspondence studies*, researchers record responses to identical pieces of correspondence from (randomly assigned) 'senders' who vary only in one dimension of their identity, such as gender or age. In one such study, researchers randomly assigned identical resumes to be sent to prospective employers, sent from either Emily or Greg (whose names communicate a white racial identity) or from either Lakisha or Jamal (whose names communicate a black racial identity). The white applicants received 50% more callbacks for interviews than blacks (Bertrand and Mullainathan, 2004). Using the same randomized assignment of letters to a sample of recipients, state legislators were more likely to respond to requests for help with registering to vote if it came from a white rather than a black sender, even if the constituent shared partisanship with the legislator (Butler and Broockman, 2011).

In *Milgram's lost-letter paradigm*, researchers drop stamped and addressed but clearly unmailed letters in public places, in a randomized pattern. The addresses on the letters vary systematically to communicate demographic or ideological characteristics about the ostensible recipients. Researchers record how many letters reach the address (which typically belongs to the research team), or more specifically, whether community members display more helpfulness in picking up the letters and dropping them in the mailbox when the letter is addressed to one type of recipient versus another. In the original lost-letter study (Milgram et al., 1965), the ostensible recipients were "Friends of the communist party," "Friends of the Nazi party," "Medical research associates," or "Mr. Walter Carnap." Passersby picked up and mailed letters addressed to medical research associates and to the neutral

individual more frequently than letters addressed to either the Communist or Nazi party, between which there were no differences in helpful mailing. Recently, in an interesting adaptation of the original paradigm, Koopmans and Veit (2013) found that regardless of the letter recipient's ethnic identity, return rates of letters were lower in more ethnically diverse neighborhoods than in more homogenous neighborhoods.

Common Methodological Problems and Solutions

Several methodological problems require special attention from researchers who embark on field experiments. Most of these problems are not exclusive to field experiments, but afflict field experiments more frequently than laboratory experiments.

Failure to treat occurs when participants assigned to a treatment never receive the treatment. For example, during a get out the vote campaign not all individuals assigned to receive a specific canvassing message are at home. To handle failure to treat, researchers can identify what is called the *Complier Average Causal Effect* instead of the *Average Treatment Effect* and exercise caution when applying their findings to society as a whole (see Gerber and Green, 2012).

Selective attrition occurs when data are missing and attrition is systematically related to potential outcomes. For example, when in a study that compares the effect of two different health insurance plans on well-being, participants with poor health drop out at a greater rate from one of the plans (e.g., if one plan requires greater cost sharing and thus places a greater financial burden on individuals with more severe health problems). To address these problems, researcher can fill in potential missing values to estimate the largest and smallest possible treatment effects, thus placing bounds around the treatment effect (see Gerber and Green, 2012). Another option is gathering additional data from missing participants.

Spillover occurs when the treatment or treated participants influence untreated participants. For example, some participants in an intervention may discuss their experience with participants in the control group. To prevent spillover, researchers can space treatments out geographically or temporally, or assign clusters of interacting participants (e.g., networks of friends) rather than single individuals to treatment and control condition. In other cases, researchers may be interested in spillover effects as an outcome. Researchers may directly study the outcomes attributable to spillover by estimating average potential outcomes under different conditions of exposure to the treatment (Aronow and Samii, 2013).

Difficulty of replication is a final challenge for field experiments due to the way in which each study must be adapted to the particularities of the local setting. This is unfortunate because replication is an important tool to establish the robustness of effects in experimentation. Some researchers have replicated their experiments in different locations, and find close to identical results in some instances (Bobonis et al., 2006; Miguel and Kremer, 2004), while being unable to replicate the original effect in others (Banerjee et al., 2010; Duflo et al., 2007).

Limitations of Field Experiments

In addition to many benefits, field experiments also have several shortcomings. It is often difficult to obtain evidence for mediating processes in the field, especially when processes are believed to occur at a microlevel, involving individual cognition or emotion. To tackle this challenge of what some call *black box causality*, it can be fruitful to combine field and laboratory experimentation. Nonetheless, it is important to note that exploring mediation is a challenge for laboratory experiments as well (Bullock et al., 2010). A related problem is that manipulating and measuring precise and narrow constructs, such as distinct emotions like shame versus guilt, can be difficult in a field setting.

While black box causality and lack of precision are obstacles at the microlevel, researchers interested in the macrolevel struggle with a different problem: it is often difficult and sometimes impossible to randomize macrolevel variables, such as institutions or elites (e.g., the gender composition of a country's congress, or aid flow). While these barriers are serious, researchers have found creative ways to address both micro- and macrolevel variables. For a study that overcame the microlevel problem by assessing nonverbal displays of emotion in a field setting (see Ditlmann and Lagunes, 2014). Another study addressed the macrolevel problem of gaining insight into institutional corruption processes by studying requests for drivers' licenses in India (Bertrand et al., 2007).

Current and Emerging Directions

As field experiments become an increasingly popular methodology, several directions for future theory and research are emerging. *Collaborations* between researchers and governmental and nongovernmental organizations provide exciting opportunities for advancing science and conducting program evaluations at the same time (Banerjee and Duflo, 2009). International aid organizations have been sympathetic to field experiments for a while (Blum, 2011), whereas collaborations with the private sector are a more recent phenomenon (Levitt and List, 2009). For example, the Abdul Latif Jameel Poverty Action Lab promotes random assignment as an evaluation tool and fosters researcher–practitioner relationships.

Combining qualitative research and field experiments is another promising direction for future research. Qualitative research methods can illuminate processes of change and thus overcome the black box problem. Qualitative efforts can range from conducting qualitative interviews with selected participants in different treatment groups to *experimental ethnography* (Paluck, 2010; Sherman and Strang, 2004).

Comparative or contextual field experiments replicate the same experiment in two different contexts. Replications can test the robustness and often improve the precisions of average treatment effect estimates. It can also advance theory. For example, Carlsson and Rooth (2011) found that the effect of discrimination in a correspondence study was higher in municipalities with aggregate level more negative than national average attitudes as opposed to municipalities with aggregate level more positive than national average attitudes. These findings advance theory by demonstrating that attitudes are at least

one important process through which discrimination effects unfold.

Combining field experiments with social networks analysis takes advantage of spillover, originally identified as a methodological problem. This approach takes into account that individuals seldom act in isolation but are part of many, often highly complex networks. Combining field experiments and social networks shows how treatment effects spread throughout different types of networks. For example, Centola (2010) randomly manipulated the topology of a network in an online health community. He found that positive health behavior spread farther and faster across clustered-lattice networks (high level of clustering) than random networks (same number of neighbors per individual but less clustering). In a different application of this approach, Paluck and Shepherd (2012) first identified all highly connected individuals in an analysis of a high school's complete social network. Next, they randomly assigned a subset of these social referents to participate in an antiharassment program. Results revealed that the exogenously altered anticonflict behavior among treated individuals influenced the perceived norms and behavior of students with ties to these treated individuals (vs the control individuals) in the network.

Internet experiments are increasingly popular, especially in social psychology (Buhrmester et al., 2011). The Internet experiments can be, though are not necessarily, field experiments. For an Internet experiment to be considered a field experiment, the intervention of interest should be a treatment that is normally carried out online, such as participation in an online health community (Centola, 2010), or in an online video game. Online participants are not automatically more representative than convenience samples such as student participants; this depends on the research question and nature of the online subject pool. In a good example of an Internet field experiment, Facebook messages were randomly suggested to Facebook users to post in their newsfeed. Of three different information messages, one was designed to put social pressure on potential voters. This message increased clicking on a public 'I voted' button and online information seeking about polling locations, relative to the two control messages (Bond et al., 2012). This intervention represents a naturalistic online field experiment, since the message treatments and the outcome variables reflect typical online behavior among Facebook users.

History of Field Experiments

Birth of Field Experiments

Field experimentation literally originated in the field, when Ronald Fisher and Jerzy Neyman conducted a series of agricultural experiments that resulted in a book entitled *The design of field experiments* (Fisher, 1935). One of the first field experiments in the social sciences tested if providing information about the election stimulates voter registration (Gosnell, 1927).

Second Half of Twentieth Century

The second half of the twentieth century was the period of large-scale, so-called social experiments such as the British Pricing experiment and the New Jersey Income Maintenance experiment (Levitt and List, 2009). More than 235 social experiments were completed at that time (for a review see Greenberg and Shroder, 2004), with the primary purpose of informing policy.

In political science, an early wave of 'get out the vote' field experiments (Adams and Smith, 1980; Eldersveld, 1956; Miller et al., 1981) followed up on Gosnell's original experiment on this topic. Unlike social experiments, the get out the vote experiments were aimed at the scientific community and are cited widely up to present. In 1963, Campbell and Stanley's famous book *Experimental and Quasi Experimental Designs for Research* (Campbell and Stanley, 1963) further advanced field experimentation. Campbell advocated a vision for an 'experimenting society' where policy decisions are based on experimentation and follow scientific principles (Campbell, 1998).

In social psychology, some early and notable field experiments include the 'stranded motorist' studies on behavior regarding helping persons in need (Gaertner, 1973), the 'lost-letter' paradigm to study cooperation (Milgram et al., 1965), the 'billboard' experiments (Freedman and Fraser, 1966), and the 'parking lot' studies (Kallgren et al., 2000) to study social influence and persuasion. The advent of the cognitive revolution, the prioritization of mediation analysis to understand psychological processes, and the requirement for multiple study packages in top journals subsequently relegated field experimentation to a secondary role in social psychology (Cialdini, 2009).

Late-Twentieth and Twenty-First Century

In 2000, Gerber and Green published what later became a landmark get out the vote field experiment that overcame many methodological limitations of prior experiments (Gerber and Green, 2000) and inspired a great number of experimental studies on voter turnout (for a review see Green and Gerber, 2008). This wave of get out the vote experiments raised the profile of field experiments in political science (John, 2013). Field experiments with explicitly theoretical as well as policy aims also blossomed in economics (Levitt and List, 2009). They became especially popular in the area of development economics, in part because international aid agencies became sympathetic to the use of field experiments (Humphreys and Weinstein, 2009). The twenty-first century is also seeing a renewed interest in field experiments in social psychology (Cialdini, 2009; Paluck and Cialdini, 2014).

Field Observational Research in Anthropology and Sociology

Abstract

Find observational research, or ethnography, has a 150-year history in anthropology and sociology. As a form of 'I-witnessing' ongoing social life, it triangulates fieldwork data preserved in notes and records with comparative social theory and documentary contextualization. The research process begins with problem and site selection considerations, access to natural behavior-stream events, and development of rapport with research subjects. As the fieldwork 'funnel' narrows, discovery procedures progress from situated listening and observation, to interviews. Fieldnotes, combined with headnotes, are later employed in constructing written ethnographies that may be assessed by canons of validity rather than reliability, which attaches more centrally to other research modalities.

Field observational research in anthropology and sociology – or the process of doing ethnography – brings the social science investigator directly to the scene of the human behavior she or he describes. It involves 'being there,' or 'I-witnessing.' So also, of course, do other forms of documentation: journalism, film, travel writing, explorer or missionary's report, even background research by a novelist. What makes ethnography distinctive as a research practice is that it forms one point of a triangular process of knowledge construction which also includes comparative social theory and documentary contextualization.

The fieldnotes that result from ethnographic discovery procedures are not merely 'written up,' but are filtered and interpreted against theoretical propositions and the comparative record of other field observational studies; they are also grounded and enhanced by historical, ecological, demographic, economic, and other documentary sources that provide background and context. As the products of this mode of research are read – monographs and articles also referred to as ethnography – they stimulate new comparative theoretical thinking, which in turn suggests further problems and interpretations to be resolved through more field observational research. Ethnographies also regularly lead to new demands and rising standards for documentary contextualization – more history, more ecological or demographic backgrounding, more attention to state policy, economic trends or the world system. This triangle of ethnography, comparison, and contextualization is, in essence, the process by which field observational research in anthropology and sociology is utilized to explain and interpret human cultures and social life.

History and Scope in Anthropology and Sociology

In 1851 Morgan published his *League of the Ho-de-no-sau-nee, or Iroquois*; combining fieldwork and comparative and theoretical interests in political organization, this book was the first anthropological ethnography. It depicted the structure and operation of Iroquois society, detailing matrilineal kinship, political and ceremonial life, material culture and religion. After formation of the US government Bureau of American Ethnology in 1879, a stream of ethnographic accounts of native American societies began, including landmark field observational studies of the Zuni by Cushing, the Baffin Island Inuit by Boas, and, after 1900, ethnographies of Plains, Eastern Woodland, and California groups by Boas' students trained at Columbia University. During the 1930s the scope broadened to include rural and urban studies in Latin America, the Caribbean, Africa, and Europe, and also in contemporary US settings.

In Great Britain's colonies, local government official or missionary fieldworkers followed the topical guidebook *Notes and Queries on Anthropology*, drafted by Oxford University theorist Tylor and others, and first published in 1874. This armchair scholar/man-on-the-spot division of labor ended two decades later when Oxford-trained Spencer collaborated in field observational study with local expert Gillen, producing their *Central Tribes of Native Australia* in 1899, and providing detailed coverage of cosmology, ritual, and social organization which revealed unheralded complexity, and which sparked theoretical work by Durkheim and Freud. In 1898 a team from Cambridge University conducted fieldwork in Torres Strait north of Australia, and member Rivers used genealogical data to probe community history, migration trajectories, marriage patterns, demography, and inheritance. Rivers and his students conducted further ethnographic studies in India and the Pacific, but their work was eclipsed by the more thorough Trobriand Islands field observational research of Malinowski, resulting in *Argonauts of the Western Pacific* in 1922 and its famous first chapter on method. Malinowskian ethnography dominated British social anthropology thereafter, and by the 1940s reshaped American cultural anthropology as well.

In sociology, there is less agreement about the disciplinary origin of field observational research methods. Conventionally, the monographs of the University of Chicago department during the 1920s and 1930s are cited (Madge, 1962): studies of itinerant 'hobo' workers, youth gangs, dancehall employees and patrons; Italians, Poles, Jews, French Canadians, Mexicans, and Chinese; and central city 'gold coast' apartment, artist colony, and rooming house dwellers. Two decades before this research, however, Du Bois used similar methods (both he and the Chicago school were inspired by British and American urban survey and settlement house movements) to produce *The Philadelphia Negro* (1899), which depicted life in an inner

city neighborhood comprised of southern migrant and northern-born African-Americans. Even earlier, Engels in 1844 studied new classes, Irish labor migration, urban spatial arrangements, symbolic attachments, and modes of observable behavior in Manchester and other rapidly industrializing British cities, although his *Condition of the Working Class in England* was not published in English until 1892.

Since the 1920s there has been much cross-fertilization between anthropological and sociological ethnography. A few of the Chicago studies were conducted by researchers identifiable as anthropologists, and the Lynds, authors of *Middletown* (1929) which credits anthropologists Rivers and Wissler for methodological inspiration, and Whyte, author of *Street Corner Society* (1955 [1943]) and influenced by Harvard anthropologists, are presented as major figures in the development of American sociology (Madge, 1962). Gluckman, a Manchester social anthropologist whose fieldwork was conducted in Africa, was influential in the development of ethnographic fieldwork by British sociologists working in schools, gangs, and factories during the 1950s and later (Burgess, 1984). In recent decades, both anthropologists and sociologists have undertaken field observational research in a wide range of overlapping settings, at home and abroad; so increasingly do scholars from folklore, education, environmental psychology, political science, and other disciplines. Ethnography, however, remains central to credentialing, teaching, publishing, and theory-construction in anthropology, while it occupies a more marginal position in contemporary sociology, or in other fields.

Selection, Access, Rapport

The selection of a particular population or site for field observational research is ordinarily related to some unanswered question or outstanding problem in social theory. Personal connections or predilections of researchers also shape this selection, but the fieldworker must justify his or her choice in terms of some significant theory to which the project is addressed. Usually this is made explicit in a written proposal for funds to underwrite the fieldwork.

While ethnography is thus lodged from conception in social theory, a comparative viewpoint also molds the fieldwork process. First, investigators acquire a cross-cultural or cross-site perspective by training and reading; when addressing any aspect of social life – marriage, leadership, ethnicity, etc. – field observational researchers recall examples of similarities and differences elsewhere. Second, the comparative perspective focuses attention on trends and transitions, not just on similarities and differences at random (which are infinite). Rather than treating each fieldwork case as unique, ethnographers place the social phenomena they study within comparative frames (foraging, horticultural, agricultural, pastoral, industrial, colon ial, neocolonial economies; cooperative, competitive, individualistic societies; gender subordination, complementarity or equality; etc.) Ethnographic results in turn provoke debate, revision, and innovation in such theorizing.

While significant theories bring fieldworkers to particular locations, actors, and activities, once they arrive they begin to observe and listen. Often they must learn to listen – by learning the language, the local vocabulary, and current verbal conventions. Field observational research now turns away from theoretical discourse to the viewpoints and concepts of the people (informants, subjects, actors, consultants) themselves. Ethnographers aim to document how the people see and talk about their everyday social activities and groupings, and about the wider worlds they live in. It is their normal scenes of activity, topics of conversation, and standards of evaluation that are the objects of field observational research.

This does not begin by announcing: 'I'm your ethnographer; when can I interview you?' Investigators must be honest about their role and sponsorship (covert field observational research remains controversial and rare), but their paramount aim is to listen and to move as quickly as possible into the natural settings of social life, the places people would be, doing what they would be doing, if the ethnographer was not there. This involves a continuing process of requesting and obtaining access to the many locations, activities, and groups that comprise the overall fieldwork arena. As ethnographers observe and listen in a wide-ranging manner, within parameters set by the significant theories that bring them there, they begin to understand culturally meaningful behavioral conventions, and to formulate culturally appropriate utterances. This indexes a second continuing process of building interpersonal rapport with informants, a topic that preoccupies many autobiographical accounts of field observational research – one of the most instructive being Whyte's, 1955 [1943] Appendix to *Street Corner Society*.

As the ethnographic process unfolds, the fieldworker must constantly make decisions about where to be, whom to listen to, what events to follow, and what to safely ignore and leave out. These decisions are guided both by the significant theories prefiguring fieldwork, and by new theories of significance that arise in the field. These latter theories – hunches, hypotheses, ideas about connections and relationships – emerge as listening and observation proceed. They suggest which persons and activities to focus upon, what places and events to attend to, and which objects and their circulation to follow. As this occurs, the fieldwork 'funnel' narrows, to use Agar's (1980) apt metaphor. The early phase of securing access and building rapport is wide, open, and nearly all-encompassing; as theories of significance emerge, pan out, or are discarded, the funnel of informants, events, and activities narrows. Goals crystallize. Research design sharpens.

Discovery Procedures: Listening

Ethnography's greatest strength is situated listening. Interviews become useful at later stages of fieldwork, but field observational research begins by listening to what British anthropologist Richards (1939) called 'speech in action.' Here the actors control topicality – talking to each other about what they usually do – and the researcher secures access to their turf – the locations they usually occupy. Early on, as rapport begins to be established, fieldworkers deliberately place themselves in a wide sampling of such situations. Then, as the research funnel narrows and other methods are deployed, the ethnographer becomes more selective about where to listen.

The importance of situated listening was emphasized memorably by Whyte. After he asked an intrusive question

during illicit gambling activities, and stopping the ongoing flow of behavior, Whyte's key informant Doc told him, 'Go easy on that "who," "what," "why," "when," "where" stuff, Bill. You ask those questions and people will clam up on you. If people accept you, you can just hang around, and you'll learn the answers in the long run without even having to ask the questions.' 'I found that this was true. As I sat and listened, I learned the answers to question that I would not even have had the sense to ask if I had been getting my information solely on an interview basis' (1955 [1943], p. 303).

Situated listening becomes the basis for understanding both what can be talked about in later conversations and interviews, and what categories and evaluations the actors use to observe and interpret ongoing behavior.

Discovery Procedures: Observing

Many veteran field observational researchers bristle when they are told that their methods are not quantitative. Using both emic categories articulated by the actors, and etic categories formulated by the community of social science observers, ethnographers count, sample, and calculate ratios, proportions, and probabilities as part of their fieldwork activities (Johnson, 1978). These countable quantities include numbers of people in events, their positions, their comings and goings; objects, inventories; and exchanges, movements, orderings, sequences, associations, assemblages, and arrangements of many sorts.

Malinowski's classic *Argonauts of the Western Pacific* (1922) incorporated his numerous observations of the interisland *kula* exchange of seashell valuables – necklaces traded for armlets – as canoes from one community arrived at another, exchanges were conducted, and then additional exchanges of items including foodstuffs, timber, greenstone, and pottery followed. Who exchanged what, the order, etiquette, volume, frequency, and other variables were all counted and analyzed. In Whyte's *Street Corner Society* (1955 [1943]) the size, composition, duration of activity, and initiation of interaction were recorded and analyzed for numerous group events; Whyte even demonstrated quantitatively a relationship between hierarchical group leadership structure and bowling scores.

Harris (1964) furnishes field observational researchers with an etic model of 'the great stream of uninterrupted behavior' that extends backward in time and unfolds continuously. He provides a technical vocabulary to operationalize recording of isolatable events and linked segments of the behavior stream – from individual body movements and their environmental effects at the most basic level, through sequences of multiactor scenes connected by actor, place, or object. Sanjek (1978) applied this approach in a multiethnic Ghanaian urban neighborhood to collect (through interviews) sequences of multiactor scenes for 40 adults, each over four-day periods, in order to test whether their social networks were structured more by common ethnicity or by class position, and in which behavioral settings ethnicity and class were stronger or weaker.

Johnson (1975, 1978) developed an observational fieldwork approach to formulate statistically valid time allocation patterns in his research among the Machiguenga of Peru. By randomly selecting actors and times for observation at their most likely location, and recording their ongoing behavior at the time of each random visit, a powerful quantitative record of how a given population allocates its activities among production, reproduction, leisure, and other categories resulted. This and similar methods have been employed in a wide range of fieldwork settings (Gross, 1984).

Discovery Procedures: Interviewing

Barth recounts of his highland New Guinea research, 'My field procedure was … to rely very heavily on observation of spontaneous, unelicited word and act. I paid particular attention to this in Baktaman questions and explanations *to each other* – in men's houses, in the fellowship of hunting and working, during initiations and other rites. Only secondarily, and with much reticence, did I ask my own questions, and then only when they seemed cast in a native pattern and received easy and natural response' (1975, p. 226).

Interviewing is problematic (Briggs, 1986). Human beings are apt to reinterpret or reformulate the past to make it conform with their ongoing sense of the present. Moreover, the ever present danger of an observer effect in fieldwork – that the presence of the observer affects and reshapes an actor's behavior and response – is especially difficult to control in an artificial one-to-one interview situation where normal social activity is suspended. Still, interviews are essential to field observational research. They are best left for later stages of the ethnographic encounter when, to use Agar's funnel metaphor, the speech events of fieldwork move from wide and open to narrow and more focused.

After the investigator has become at ease with the language and local codes and references, and has successfully gained access to natural conversations and amassed a stock of cultural knowledge via situated listening, deliberate intervention into speech events may begin. These steps may be graded from least to most intrusive and controlled.

1. Still on the informants' turf, and still in the accustomed activities of daily life, the field observational researcher begins to enter natural conversations as a speaker, and begins to shift topicality to her or his own interests. This process starts gently, by moving appropriately into rounds of chatting, gossiping, and ordinary comment. As cultural competence increases, and as theories of significance emerge, the fieldworker attempts to direct conversations by introducing questions and suggesting topics for responses from informants.
2. After an initial period of fieldwork – a few months perhaps – arranged interviews may begin. This class of speech events is disruptive – the informant is removed from her or his turf, either to the ethnographer's household or office, or by transforming an everyday location into a scene of ethnographer–informant dialogue – an activity that would otherwise not be occurring there. Typically the earliest of these deliberate breaks in time–place behavioral flow reserve topicality for the actor. In such open-ended or discovery interviews, the informant is encouraged to move the conversation according to his or her own interests.
3. In later and more productive interviews, the ethnographer begins to assert control. General topics are introduced, allowing informants to expand freely upon their own points

of view and knowledge. In more structured ethnographic interviews, topicality is more firmly shaped and directed by the fieldworker; informant responses now move away from orations and free commentaries and to more specific responses to questions.

4. In the most focused forms of interviewing, the ethnographer controls both turf and topicality as fully as possible. Questionnaires and interview schedules may be used, and the objective is to obtain particular types and pieces of data. These may include household interviews, psychological tests, or reports of disputes, or may encompass repeated interview sessions to secure lengthy life histories, with the fieldworker now guiding the subject according to preset standards of scope and comprehensiveness.
5. Though not a major part of ethnographic practice, in some instances, and when still on the informants' turf, the fieldworker may ask direct and pointed questions, and attempt to secure precise pieces of data for his or her records. Interventions of this sort are especially dangerous – the inappropriateness of such seizures of topicality in everyday settings may be jarring to the actors. Typically speech events of this sort occur in the final days of fieldwork, when local rapport is at its peak, research goals are most pressing, and the fieldwork funnel approaches its vanishing point.

Notes and Records

The production of notes and records (Sanjek, 1990) begins to move the field observational research process toward its ultimate written products. Focused interview sessions with seated informants often permit direct transcription of verbal statements, but in open-ended and ethnographic interviews, brief written notes – what Ottenberg (in Sanjek, 1990) terms scratch notes – are taken during the session, and these form the basis for the construction later of fuller written fieldnotes. Fieldworkers often go through this two-step process even when interviews are tape recorded, both as a backup to and index of the taped session, and because of the analytic gains many ethnographers note in transforming their scratch notes into fuller descriptive fieldnotes.

In field observational research in natural behavior stream settings, similar brief jottings may be inscribed, but major attention is directed to the event in progress. Often it is not even possible to record scratch notes, and both they and fuller fieldnote description occur later. Mead (1977) wrote about the nagging pressure to type up fieldnotes from scratch notes, and about the danger of scratch notes growing 'cold' when this was delayed, even by one day. But she also wrote of the satisfaction of being caught up with this work, and of the importance for later ethnographic writing of the insights gained in moving from scratch notes to descriptive fieldnotes.

Ottenberg sees this process as the interaction of scratch notes and headnotes – the stored memories and interpretations that arise from direct participant observation as filtered by the ethnographer's overall theoretical stance. Headnotes form an essential complement to fieldnotes (and to more formal fieldwork datasets or records). Headnotes are employed to make sense of one's fieldnotes when they are re-read later for ethnographic writing projects. The importance of headnotes is particularly evident when one ethnographer attempts to use another's fieldnotes, and quickly realizes how difficult it is to understand them without headnotes of one's own (Sanjek, 1990).

Fieldnotes typically are kept in running chronological order, and may minimally be indexed separately by actor and topic. Additionally, field observational researchers often generate records, or well-defined sets of data organized by topic, person, or other category. These may include records of household composition, land holdings, ritual performances, life histories, folktales, etc. Sometimes decisions to collect sets of records are part of the initial research design, and preset forms to enter such data may be brought with the investigator to the field setting. In other cases, a decision to collect a systematic body of records develops during fieldwork, often emerging within general running fieldnotes and then being separated out in new record files.

Fieldnotes and records present ethnographers with great masses of information – hundreds, even thousands of pages – that while being accumulated may be arranged only by chronological order or by topic. Malinowski (1922) urged that ethnographers constantly re-read and begin to organize and analyze their notes while still conducting field research, but commonly the more focused work of indexing them occurs when fieldwork is over. As ethnographers then turn to ethnographic writing, they readdress the theoretical discourse they turned away from in fieldwork. Fieldnotes and records must now be related directly to the comparative and contextual points of the knowledge-construction triangle.

Canons of Validity

Field observational research aims to maximize validity – 'the degree to which scientific observations actually measure or record what they purport to measure' – rather than reliability – 'the repeatability, including interpersonal replicability, of scientific observations' (Pelto and Pelto, 1978, p. 33). Reliability is valued in survey, medical, and product safety research. In ethnography, restudies to assess change may be conducted, but independent investigation of the same locale or population is unlikely or impossible.

Validity depends on the intensity and depth of field observational research, but it always remains a goal rather than a property that can be independently measured (Wolcott, 1995, pp. 167–70). A quantitative, and highly reliable, randomized sample study that investigates the gender, ethnicity, class, and other characteristics of the five best friends of members of a given population would be less valid than one in which cultural meanings and categories of friendship were first discovered through listening to natural conversations or eliciting such information in interviews. In the case of Indian immigrants in New York City, for example, the 'five best friends' study might miss entirely the category of *rakhi* ritual friendships between adult males and females which are affirmed in an annual festival where the man ties a flower bracelet on the woman's wrist.

If validity remains important, but elusive, how can it be assessed in field observational research results? Sanjek (1990, pp. 393–404) proposed three canons of validity by which

ethnographic writing may be evaluated. The first is theoretical candor, the openness with which the ethnographer addresses the significant theories, and even more, the local theories of significance that structured the fieldwork process. A second canon calls for explicit depiction of the ethnographer's fieldwork path – the number of informants from whom information was obtained, in what ways, and their relationship both to the wider population the field observational study concerns and to each other. A third canon concerns information about the fieldnote evidence itself: not simply 'how much' and its basis in listening, observing, or interviewing, but more significantly the precise relationship of notes and records to the written ethnography. Some ethnographies utilize fieldnotes directly, even masses of them; others, for rhetorical or narrative purposes, do not, and need not. What matters in the end is that readers of field observational research have a clear picture of what the ethnographer did and why, who they talked to and learned from, and what they brought back to document it.

Field observational research produces results that can be obtained in no other way. This ethnographic tradition entails that 'the description of people's activities, their interactions with each other, [and] their verbal behavior' be 'copious and detailed'; 'cumulative development … consists above all in the fact that such data, provided they are adequate, never become obsolete and can be used by analysts … in researching questions not visualized by the researchers who collected them' (Anglin, 1979, p. 49).

Abstract

Developed in sociology by Pierre Bourdieu, the concept of field is a heuristic tool for exploring the differentiation of social spheres of activity. The article first traces the origins and genesis of the concept in Bourdieu's theory. It then turns to the general theory of fields that Bourdieu has elaborated, based on empirical research on the literary, the scientific, the religious, the academic, and the political fields. The theory of field has become a research program for a group of scholars who examined issues such as the relations between fields, the use of field theory for comparative purpose, and the geographic borders (national or transnational) of fields. The last section presents other field theories more or less inspired by Bourdieu.

The concept of the field makes it possible to circumscribe individuals' action at the mesolevel, in differentiated social spheres with their own rules of the game and specific interests. Field theory was thoroughly developed by Pierre Bourdieu beginning in the 1960s in order to make sense of the process of social differentiation of activity spheres that comes with the division of labor, while at the same time implementing a relational and topographical approach of the social world. Field theory served as a research program (in Imre Lakatos' sense) and resulted in a great deal of research on the fields of politics, economics, religion, the academy, law, philosophy, literature, art, intellectuals, publishing, sport, etc. In the United States, other uses of the concept of field have appeared, the first of which was the notion of 'organizational field,' theorized by Paul DiMaggio and Walter Powell during the 1980s within a neoinstitutionalist approach. Later, the notion of 'strategic action field' was devised by Neil Fligstein and Doug McAdam in order to combine the neoinstitutionalist approach with collective action theories.

The Origins and Genesis of the Concept of Field

The concept of field is borrowed from theoretical physics: it apprehends relations between elements within a space seen as a force field, according to the laws of attraction and repulsion. It was transposed in psychology by the Gestalt theorists, especially Wolfgang Köhler, who underscored the interdependency of elements in perceptual experience and developed a topographic approach (Levi Martin, 2003). Kurt Lewin adapted it to social psychology in order to consider the interactions between an individual and his or her environment.

It is in this sense that Bourdieu introduced it in sociology, where the abstract concept allows for the methodological autonomization of a space of activity, provided that – as Bourdieu specified for the fields of cultural production – the historical conditions of its autonomization have been studied (Bourdieu, 1971c). The use of the concept of field responds to a double problem. First of all, how does one consider the historical process of the differentiation of social activities that accompanies the division of labor without lapsing into a functionalist approach? There is indeed nothing ineluctable, and nothing mechanical, about this double process. The autonomization of an area of activity generally results from the struggle led by a group of specialists (legal practitioners, for example) in order to obtain social recognition for their authority and jurisdiction in a given area, introducing a rupture between professionals and nonspecialists (for example, between clerics and laypeople). The theory of fields systematizes the analysis of this process, identified by Max Weber, and draws from it methodological consequences – that is, it is possible to autonomize a field as an object of study.

However, this autonomy is always relative. Bourdieu borrows the concept of autonomy from Marxist theory, where it was introduced as part of the debate on reflection theory, which considered works as a superstructure reflecting social conditions. Certain theorists indeed suggested that literary and artistic works were not a simple reflection of the social world, but rather that they expressed a vision of the world that could echo the contradictions that were simmering within the conditions of production. However, Bourdieu criticized these thinkers' failure to consider the mediation that fields of cultural production exert with regard to economic and social conditions: it is there, in what Bourdieu calls a 'field effect,' that he situates the relative autonomy of these spheres. Works indeed bear the marks of their own conditions of production. Cultural producers are engaged in a competitive struggle that abides by rules and specific interests irreducible to economic, political, and social interests. Regarding social space, the 'field effect' produces a 'refraction' effect, another concept Bourdieu borrows from physics, wherein exterior constraints are retranslated according to the particular logic of the field in question. This particular logic derives partly from the structure of the field, and partly from its history. Such an approach makes it possible to avoid, on the one hand, sociological reductionism and, on the other, approaches that examine only the internal contents of a single text (this is just as true for cultural production as it is for science, philosophy, and law).

The structure of the field is defined according to the (unequal) distribution of specific capital in the field: agents endowed with the highest amount of specific capital occupy dominant positions, whereas those who possess less, often newcomers, occupy dominated positions. Such a topographical approach breaks with substantialism (drawing on Ernst

Cassirer's book *Substance and Function*) and with interactionism (namely with symbolic interactionism, but also with spontaneous interactionism, which prevails in literary and art history); in contrast, it is structural (relational) and objectivist: united by their competition for the same issue at stake, that is, acquiring specific capital, agents are defined objectively in relation to one another independently of the interactions between them – interactions that an objectivist analysis makes possible, moreover, to explain. In this regard, network analysis, which is purely descriptive, becomes meaningful in light of the objective properties of individuals.

Though the theory of field and its conception of social space are indebted to the structuralist method, which Bourdieu uses not only to a group's world vision but also to analyze social relations themselves, he conserves from Marxism a dynamic conception of these relations, which derives from their agonistic dimension. The competitive struggle indeed determines the principles of opposition that structure the field and determines antagonisms and alliances according to the laws of attraction and repulsion (Bourdieu, 1984: pp. 113–120). These principles of opposition also create structural homology among fields. The first factor opposes the 'dominated' to the 'dominants': the dominants usually tend to preserve the dominant definition of the activity in question ('orthodoxy'), while the dominated tend to contest it ('heterodoxy'). Drawing on Max Weber's sociology of religion, Bourdieu (1971a,b) systematizes the opposition between priest and prophet, deeming it paradigmatic, and transposes it to the fields of artistic production, where it is transplanted to the opposition between established and avant-garde cultural producers (see Bourdieu, 1971c). A second opposition places the upholders of the autonomy of field, which is based on peer judgments formulated according to specific criteria for determining the symbolic value of products, against those who tend to import into it heteronomous – ideological, or economic – constraints.

These positions evolve based on various factors, some of which, such as crises or politicization, are exogenous (May 1968, for example) and some of which are endogenous, such as internal struggles and social aging. Whereas exogenous factors may contribute to the synchronization of fields (as with May 1968; see Bourdieu, 1992a), endogenous factors impose a temporality that is specific to each field, and this constitutes another sign of fields' relative autonomy. Moreover, relatively autonomous fields are characterized by their autotelic nature, or their self-referentiality – that is, by the reference to their own history. Such is the case for fields of cultural production (literary, artistic, musical) as well as scientific and legal fields, where past problems and solutions cannot be ignored by agents, at the risk of their exclusion from the field.

Field therefore consists in a 'space of possibilities' ('*espace des possibles*') where 'position-taking' ('*prise de position*') – choices between different options more or less constituted as such – are defined by significant gaps, according to the model of structural linguistics, gaps that assume their meaning in relation to the history of the field (for example, the opposition between tonal and atonal music, or between analytic and 'continental' philosophy). For this reason, in Bourdieu's eyes the subject of the work is neither the individual nor the class, as the Marxist perspective suggests, but rather the field as a whole.

The notion of a space of possibilities is in this sense linked to Foucault's concept of the 'field of strategic possibilities' (Foucault, 1969), but it is set apart by the very specific use Bourdieu makes of the concept of 'strategy' in order to apprehend agents' differentiated forms of investment in this space of possibilities. Far from supposing rational, reflexive, or even cynical action, the concept of strategy refers, in Bourdieu's theory of practice, to the extent to which agents are able to improvise according to the exterior constraints they must contend with and to their dispositions: in other words, the latitude they have to maneuver. The concept of strategy aims to describe the encounter between a social trajectory and a space of possibilities. This trajectory is largely determined by an individual's habitus, that is, by the social structures he or she has internalized throughout the process of socialization, in the form of dispositions that in turn structure his or her schemes of perception, action, and evaluation (taste). As such, the question of the relation between the social properties of individuals and their stands or position-taking is not a given but rather a central object in the study of field functioning.

Toward a General Theory of Fields

From the 1970s onward, Bourdieu developed a general theory of fields. The project was not realized in his lifetime, but many traces can be found, from the seminars and talks he dedicated to it during this period (Bourdieu, 1984, 2013a) to the research that he and the members of his team carried out on particular fields: literary, religious, scientific, political, legal, academic, philosophical, artistic, economic, editorial, not to mention the field of *haute couture*. Because it is impossible to take account of all of the research that puts the concept to work, we will limit ourselves here to discussing, on the one hand, the contribution field theory has made in the study of different areas of activity and, on the other hand, the way these fieldworks have enriched or redefined the general theory.

Bourdieu began investigating the fields of cultural production as early as the 1960s (Bourdieu, 1966). He aimed to establish a 'science of (creative) works' ('*une science des oeuvres*') that would overcome the alternative between internal analysis, represented at the time by New Criticism and structuralism in particular, and external analysis, which was split between the singularizing, biographical approach (see Sartre's biography of Flaubert, entitled *The Family Idiot*, for the most masterful example) and the reductionism of Marxist reflection theory. Against the myth of the 'uncreated creator' ('*créateur incrée*') of Romantic ideology, the theory of fields reminds us that cultural producers are not free from social determination, and that they do not produce works in isolation, but, against the backdrop as propounded by the reflection theory, it emphasizes the fact that these determinations are mediated, refracted by the field, i.e., by a preexisting space of possibilities, which needs to be reconstructed in order to account for the principles of their esthetic choice.

These considerations raise two historical questions. The first concerns the autonomization process of these fields which, according to Bourdieu, derives from three conditions: the appearance of a group of producers specializing in a given activity (literature, painting, music, sport); the existence of

specific authorities playing a major role in the recognition and consecration process; and the formation of a market of symbolic goods, which reverses the temporal order that patronage established between demand and supply (Bourdieu, 1971c). Though the emergence of such a market was observed as early as the end of the eighteenth century, the autonomization process did not occur at the same time or in the same fashion in literature and painting: while the rise of publishing and the liberalization of printing in the early nineteenth century gave writers up to the ruthless law of the book market, sanctioned by sales figures, the art market was regulated strongly until the middle of the century by a single body, the Académie des Beaux-Arts, which assumed the monopoly on consecration through control of access to the Salon, the only public gathering where works were exhibited and sold (Bourdieu, 2013). The development of societies of artists, which resembled a kind of sales cooperative, and the bohemian style of life adopted by the cultural producers who were excluded from the academic system – and who multiplied in number as schooling became more and more common – nevertheless contributed to the emergence of a market on the margins of this system.

While the artistic field was being formed against the State, the guarantor of the existence of the academic system, the autonomy of the literary field needed to assert itself with regards to the market, which had challenged the monopoly of the Académie française over literary consecration. As Bourdieu describes in *The Rules of Art* (1992a), against the pole of large-scale production and circulation ruled by the logic of the market, a pole of small-scale production formed in the middle of the nineteenth century, imposing the primacy of the symbolic value of works, established on the basis of peers' specific criteria for assessing its aesthetic quality. The economy of symbolic goods is a 'reversed economy' that opposes to short-term profitability the slow process of recognition of works on the long term. The process is liable to lead to the 'canonization' of certain authors or artists through the integration of their works, turned into 'classics,' as part of the national and universal cultural heritage, namely through the intervention of the educational system (Bourdieu, 1993).

In France, this reversal was carried out under the Second Empire by the proponents of 'art for art's sake,' who were as opposed to 'social art,' that is, to engaged art, promoted by left-wing writers, as to the École du bon sens (School of common sense), which gathered 'bourgeois' authors, who were close to the dominant fractions of the dominant class. Bourdieu analyzes the conditions of the conquest of autonomy via this double break, carried out by Flaubert and Baudelaire. He qualifies the latter as a 'nomothete' in that he established a new *nomos* in the literary field, characterized by its independence from external powers – both economic or political and by anomie. In liberating themselves from the bourgeois in order to affirm the prevalence of pure aesthetics, and, concurrently, an ethos combining rigor at work and anticonformism, Baudelaire and Flaubert achieved a 'symbolic revolution' that had everlasting consequences for the literary field (Bourdieu, 1992b).

How do such 'symbolic revolutions' come about? This is the second historical question raised by the study of fields of artistic production, which is also relevant to the fields of science and even *haute couture* (Bourdieu, 1984: p. 200). The most in-depth formulation of this question is found in the lecture courses on Manet Bourdieu (2013b) delivered at the Collège de France. These symbolic revolutions are difficult to apprehend, due to the fact that our own categories of aesthetic perception result from them. It is therefore necessary to reconstitute the vision of the world that predated the revolution in order to bring to light the principles that previously drove academic aesthetics. This academic code, backed by the state monopoly, was destroyed by Manet. In opposition to the importance granted to technical mastery (perspective, relief, clair-obscur) and the 'finish,' Manet worked the canvas in its bidimensionality – which meant he would transgress the laws of perspective and relief – and ennobled the sketch, seen by the masters of the Académie as a mere first step before 'invention,' or the finishing process. In addition, Manet challenged the classical, socially driven, hierarchy of objects. He also replaced the omnipresent reference to history by a reference to the history of art, recognizable only by insiders. Such a preference led him, if not to empty the work of all of its meaning, then at least to render it ambiguous, therefore breaking with the principle of readability (or the message) and going so far as to engender bewilderment and contradictory interpretation – and, sometimes, scoffing and scandalized scolding.

A thorough analysis of the transformations in the conditions of production – at once technical (the invention of tubes of color that make it possible to paint outdoors), morphological (the growth of the artist population), and economic (the formation of a market running parallel to the academic system) – helps to avoid the biases of idealism and individualism, but does not suffice to explain the symbolic revolution achieved by Édouard Manet. A sociological analysis must take into account Manet's dispositions: the generous economic, cultural, and social resources he possessed as the son of a judge and descendant from a line of legal professionals, his training within the academic system, his vast pictorial culture, the freedom his private income gave him, and his dense network of relations, high society on one hand, and cafés and the bohemian crowd on the other. This extraordinary concentration of assets, linked to what Bourdieu calls a 'cleft habitus' split between the two poles (economic and cultural) of the field of power, predisposed Manet to accomplish this revolution. Like all 'symbolic revolutions,' this one was defined not by destruction but by the integration of that which preceded it: the break occurs in continuity, as illustrated by the practice of pastiche. As such, even in spheres where, in contrast to the bureaucratic world, positions are yet to be created, the most innovative practices fit in a dialectic relationship with the space of possibilities.

The field of *haute couture*, or high fashion, offered an equally rich ground for observing the logic of fields. Producing belief in brand fetishes according to a process Bourdieu compares to Mauss' conception of the way magic functions, the field was structured at the time by an opposition between 'rive droite' (Balmain) and 'rive gauche' (Scherer). Courrèges achieved a symbolic revolution by replacing discourse on fashion with a reflection on the lifestyle of the modern woman, which in his view was meant to be carefree, comfortable, and relaxed. Courrèges was thus synchronizing internal revolution and social

transformation. Such a synchronizing process is typical of symbolic revolutions according to Bourdieu (1984: pp. 196–206).

This model of analysis also serves to reflect both upon the conditions of existence needed for a relatively autonomous scientific field where peer judgments prevail over heteronomous logic (ideological or economic) and upon scientific revolutions (Bourdieu, 1976, 1991, 1997, 2001). The scientific field is different from cultural fields of production in that its public is made up primarily of peers. This characteristic exacerbates the competition for acquiring specific capital. Emphasizing this particularity enables Bourdieu to refute relativism and instead propose a 'historicist rationalism' founded on the theory of fields. Introducing social, political, and economic interests in the analysis of the conditions of scientific knowledge may indeed lead to relativism. Thomas Kuhn's model of scientific revolutions has paved the way to such a relativism (though Kuhn himself did not subscribe to this view). The sociology of science underwent a shift from rationalism founded on the professional norms that dictate the scholarly ethos (universalism, communalism, disinterest, skepticism) according to Robert Merton's functionalist model, to the relativism of the sociology of interests and of constructivist approaches. Though Bourdieu breaks with the enchanted vision of a scientific community acting in harmonious cooperation in the universal interest of science, he contends that fields' relative autonomy and their imposed rules guarantee the universal scope of scientific knowledge – all the while reintroducing the power relations and extrascientific interests that occur in these spheres. The scientific field produces an interest in disinterest that, linked to the collective control of peers, is one of the conditions of its autonomy, even though this autonomy is relative. Analyzing the way of the scientific field functions has an added value in that it contributes the reflexivity that scholars have with regards to their own activity.

The 'field effect' can be observed particularly in the highly conceptualized field of philosophy, where mastering references from the past is the necessary condition for access to recognition by peers. The analysis of Martin Heidegger's political ontology (1975, 1988), resituated in the field of the ideological production of his time, thus reveals the conservative, even reactionary ethicopolitical schemes which, like most of the important figures experiencing a decline in their position in the field of power, he shared with the 'völkisch' atmosphere and led to his adherence to Nazism. However, Bourdieu also insists on the transubstantiation that the process of philosophical conceptualization forced these figures to go through, euphemizing them to the point of unrecognizability: the field's specific censorship is at the origin of this operation of 'philosophical sublimation.' As such, the field effect provides 'an objective foundation to the illusion of absolute autonomy' (1988: p. 10), all the while making it possible to overcome the alternative between an ideological reading of a work and a purely philosophical reading – an alternative that commenters of Heidegger's work still debate today.

The study on Heidegger followed a large empirical study on the academic field, published in 1984 under the title *Homo Academicus*, which allowed Bourdieu to develop his research program on the scientific field (Bourdieu, 1992a). Focusing on the French academic field of the 1960s, the study is based on a prosopographic survey combining individuals' social properties and indicators of the positions they occupy in the field. The indicators distinguish between various kinds of capital within temporal (heteronomous) forms of social recognition and symbolic (autonomous) ones: academic power, scientific power, scientific prestige, intellectual notoriety. Institutions, mainly the University, research organizations, and the Collège de France are conceived in this model as variables (affiliation with a given institution as an indicator of an individual's position) and as agents in and of themselves in the field. A Multiple Correspondence Analysis, the best-suited method for field analysis, was applied to the prosopographic data. The academic field appears to be structured according to the opposition between a temporally dominant pole of faculties of law and medicine, and a temporally dominated pole of science faculties, with faculties of letters and the human sciences located between the two. Advantageous sites for observing the struggles between these two forms of academic power, temporal and symbolic, given their intermediary position, humanities faculties are divided between a pole of university academics more concerned with the reproduction of the institution, and therefore toward the exercise of temporal power within the cultural order, and a pole of agents oriented toward research, affiliated most often with prestigious but marginal institutions such as the Collège de France. The agents in this second group tend to be 'producers' rather than 'reproducers,' and are also more often internationally oriented than the first group. The study therefore made it possible to differentiate between two types of consecration, temporal and symbolic, which have equivalents in the fields of cultural production: public success and institutional recognition (prizes, Academies) on the one hand, and on the other, acknowledgment by peers and specialized critics (criticism being in and of itself a field, structured by homologous oppositions).

A field's degree of centralization varies depending on an institution's capacity to monopolize the power of reproduction within the limits of the institution such as the Catholic Church, the University, or the academic school of Beaux-Arts in France. When an institution holds a significant monopoly in a given field, one speaks of a 'body' ('corps') – in the sense of the *Corporatio* of Medieval Canonistas – rather than of a 'field' (Bourdieu, 1985a, 1999, 2013b). Competitive examinations, numerus clausus, are means of controlling access to a field and may potentially lead to the field's being transformed into a body, via the homogenization of social recruiting and the instilling of an 'esprit de corps.' However, it is rare that the social recruiting in a field is so homogenous, and differences in status often generate principles of structural opposition, such as those that arose between the Académie des Beaux-Arts and bohemian painters, or between theoretical law professionals and law practitioners, according to an opposition Bourdieu borrows from Weber.

One of the advantages of field theory as compared with the sociology of professions is that it considers activities – even when they have reached a certain degree of autonomy – as still being relatively heteronomous (for example, the way in which class relations are refracted in the field through the habituses) and as being more or less heterogeneous. This heterogeneity may result from work conditions and from status (for example, independent, salaried, and civil servant statuses may

coexist within the same area of activity) or from social recruiting (social origins or training that set Oxbridge alumni apart from others, for example). Masked by professional ideology, such splits are often inherent in the power relations that structure fields and the internal struggles at the root of their transformations. For instance, the field of law in France during the Ancien Régime differed among the State law practitioners, who formed the bureaucratic pole of law, law officers, who claimed a certain autonomy from the king's authority, and the lower clergymen of the law, who managed during the French Revolution to reverse the hierarchy of power relations with the Nobles of the Gown – to whom the first two groups belonged – and succeeded in imposing the notion of the Nation-state (Bourdieu, 2012).

Another characteristic that results from the process of field autonomization is the break between professionals and nonspecialists by which laypeople are excluded from activities because their judgment is delegitimized. The dispossession of the nonspecialists, which has its roots in the religious model wherein clergy are distinguished from laypeople, may be observed in numerous professional areas (law, medicine, architecture, science, sport) and particularly in the political field. In his studies on the latter, Bourdieu analyzes the field's phenomenon of representation and attendant delegation, a phenomenon that is at the core of the monopolization of politics by professionals (Bourdieu, 1977, 1981, 2000a).

Together with the economic field, the field of politics is a dominant field within the field of power, which, for its part, is structured by the opposition between holders of economic and political capital and those who possess mainly cultural capital (Bourdieu, 1979). With the help of neoliberal ideology, the economic field tends more and more to subordinate other fields, namely the political field (through New Public Management), the journalistic field (Bourdieu, 1996), and fields of cultural production (through the logic of concentration and merging acquisition of the culture industry, the effects of which Bourdieu studied in the French publishing industry during the 1990s; Bourdieu, 1999), by imposing its logic of profitability. Subjection to this logic threatens the autonomy of these fields in reinforcing the heteronomous pole to the disadvantage of the autonomous pole. It also raises the question of the relationships between fields, which will be examined in the following section.

Uses of the Concept of Field and Methodological Issues

Having provoked much empirical research, the concept of field brought to light methodological and theoretical questions we will briefly expose here. A good amount of this research dealt with the literary field, but significant research has also been carried out on other fields (the field of academics, politics, law, journalism, art, cinema, as well as on disciplinary fields such as philosophy, economy, sociology), and though much of this research has focused on the French case, several significant inquiries have also been conducted on other countries, such as Sergio Miceli's (1981) pioneering research on the conditions of emergence of the Brazilian intellectual field.

Analyzing a field requires three operations: the study of specific authorities; the distribution of the social properties of individuals according to the positions they occupy within the field; the reconstitution of the space of possibilities (and the space of effective positions taken). A series of prosopographic surveys were dedicated to French writers in the nineteenth and twentieth centuries, and included studies on authorities playing a role in literary recognition, and on schools or literary movements (Ponton, 1977; Thiesse, 1991; Sapiro, 1999). In the wake of Bourdieu's analyses of Flaubert and Baudelaire, other studies have focused on a central figure: Sartre (Boschetti, 1985), Beckett (Casanova, 1997), Apollinaire (Boschetti, 2001), Mallarmé (Durand, 2008), and Kafka (Casanova, 2011). Parallel research has been carried out on the German literary field at different periods (Joch and Wolf, 2005; Tommek and Bodgal, 2012).

Substantial research has also been dedicated to the French academic field. A comparison of the social recruitment of the literary and academic fields at the beginning of the twentieth century shows that writers are generally better endowed in terms of economic and cultural inherited capital than Parisian university academics (Charle, 1990). The articulation between the processes of autonomization, professionalization, and specialization during the Third Republic coincided with the emergence of a body of philosophy professors and a philosophy book market separate from the remainder of literary production (Fabiani, 1988). The contemporary field of economics is structured around the opposition between, on the one hand, 'pure' economists (neoclassical and regulationalist) endowed with strong scientific capital and, on the other hand, those with temporal resources provided by the 'political' positions they occupy as consultants, analysts, or within firms (Lebaron, 2000).

Bourdieu's reflection on the problem of political representation paved the way for a series of studies in political science on the social properties of political professionals and their variations in time and space (Gaxie, 1980), and on the larger group of individuals involved in political work: consultants, activists, pollsters, communication specialists, etc., whose growing importance stems from the increasing dependence of the political field with regard to the field of media. In addition, Bourdieu's conception of the State as a *metafield* provides new perspectives for renewing the study of public policy (Dubois, 2014).

More broadly, the question of the relationships between fields has been raised in a number of studies: subordination (for example, intellectual production did not begin to gain autonomy from the religious field until the eighteenth century), dependency, hierarchy (between disciplines within the academic field, for example), and exchange (between the literary and artistic fields). Studies on the politicization of the intellectual field at times of crisis and the resultant loss of autonomy, such as in the case of the Dreyfus Affair (Charle, 1990) and furthermore during the German Occupation (Sapiro, 1999), show that political stands ('position-takings') are strongly linked to the positions agents occupy in their field of reference, which confirms the refraction effect the field exerts on external constraints, all the while revealing the heteronomous role played by certain authorities such as the Académie française, located at the intersection of the intellectual field and the field of power. This structural homology between positions in the literary or intellectual fields and political stands is also manifested in the various forms of politicization at different poles of the literary and intellectual fields, depending on the nature of the position

(dominant or dominated), the degree of autonomy, and the degree of specialization insofar as the intellectual field is concerned (Sapiro, 2003a, 2009a). The heteronomous logic resulting from subordination to the religious and political fields were dealt with in the case of French Catholic intellectuals (Serry, 2004) and French Communist intellectuals (Matonti, 2005). The relations between the journalistic and economic fields were examined namely within the prism of the field of economic press (Duval, 2004; on the journalistic field, see also Benson and Neveu, 2005).

The historicity of fields raises the question of their genesis and temporality. Some scholars trace the start of the literary field's process of autonomization back to seventeenth century upon the appearance of lists of best writers, claims for royalties, and the officialization of the Académie française, granted by the king the power to legislate on linguistic and literary matters (Viala, 1985). The periodization proposed by Bourdieu in *The Rules of Art*, placing the conquest of literary autonomy in the mid-nineteenth Century, is therefore questioned (Saint-Jacques and Viala, 1994). Additionally, it may appear paradoxical that the autonomization of the literary field goes through a reinforced dependency on the State symbolized by the officialization of the Académie française (Jouhaud, 2000). The same is true for the artistic field, which the State raised to the status of liberal art upon creating the Académie des Beaux-Arts. However, in both cases, though there exists a specific authority, as well as more or less specialized producers in the field, the third condition – the existence of the market, which makes it possible to escape state control – is lacking.

The fields of cultural production are thus situated between the state and the market, with more or fewer constraints depending on the regime and economic conditions. Though the appearance of the market allowed for autonomy from the State, the State is capable of providing protection from economic constraints in the form of subvention policy (Sapiro, 2003b). Research on Communist regimes, wherein the power of consecration was monopolized by a body controlled by the Communist Party, the Union des écrivains, has nevertheless shown that forms of relative autonomy could manifest themselves even in contexts of strong heteronomy and state dependency (Dragomir, 2007). Moreover, autonomous logic exists even in the most market-dependent fields of cultural production such as the field of cinema, also structured upon the opposition between the poles of large and small-scale circulation (Duval, 2006). The small-scale circuit in France benefits from heavy state support; as in the small-scale publishing field. Bourdieu (1992b) analyzed the process of autonomization of a small-scale pole of production with regards to the market; the study of literary trials provides rich grounds for understanding the heteronomous logic that continued to weigh on literature and the social expectations from writers, as well as the processes of progressive recognition of the field's autonomy from the State from the twentieth century onward (Sapiro, 2011). The process of autonomization in the literary field should, furthermore, be situated within the context of the division of intellectual labor that was on the rise in the nineteenth century (Sapiro, 2012a).

As mentioned, the relatively autonomous temporality of fields becomes blurred during moments of crisis or politicization, which may produce synchronization effects. These moments raise the question of how changes occur. Do changes obey previously instated logic, as certain research suggests (Sapiro, 1999; Gobille, 2005)? By the fluidity their circumstances engender, do crises create their own dynamics undetermined by the field's previous states (Dobry, 1992)? This rationale, particular to crises, is observed in the reworking of alliances and the ensuing reconfiguration of power relations, but the logic by which these reconfigurations occur are not random. Rather they may be explained according, on one hand, to the issues at stake in the field, and, on the other, to the dispositions and resources of its agents (Sapiro, 2012b).

The concept of field is a powerful heuristic tool for comparison, whether in diachronically comparing different states of the same field (for example, the French field of power in the 1970s and in the 1990s, when economic power took precedence over cultural power; Denord et al., 2011), or in synchronically comparing the principles of structuring for one field in two countries (for example, the place of translations in the French and American fields of publishing; Sapiro, 2010). However, in order not to fall into the trap of methodological nationalism, international comparison must take into account, on one hand, the exchanges between national fields, and, on the other, the power relations in which they are embedded (Sapiro, 2012c). These international power relations indeed condition the circulation of symbolic goods and the models between national cultures (Heilbron, 1999; Sapiro, 2008). The phenomena of importation and reception must also be brought into the perspective of the target culture (Bourdieu, 2002), as illustrated by research on the importing into France of legal theories (Hauchecorne, 2009) or literature from Eastern Europe during the Communist period (Popa, 2010). The study of Latin America's introduction of neoliberal economics and the philosophy of human rights has brought to light the outcomes of the process of globalization (Dezalay and Garth, 2002).

Transnational approaches have nevertheless raised the question of the geographical limitations of fields. These problems have come to the fore namely in connection with linguistic areas, and particularly the Francophone literary space (Bourdieu, 1985b; Aron, 2005). Later, other transnational spaces were taken into account. Though much research on fields has been situated within a national framework, Bourdieu never specified that fields were necessarily circumscribed by a Nation-state's borders. Borders are not given; rather they evolve with time and are constantly being reexamined. As a result, it is up to the individual scholar to construct them. The nationalization of professional fields and fields of cultural production is a historical fact connected to the monopolization of education and to state control of access to professions (varying from country to country) as well as to the construction of national identities (Sapiro, 2013). However, these national cultures were formed with regard to one another, and they rapidly made up an international space ruled by bodies such as the League of Nations, then the United Nations, and, for culture and science, the International Committee on Intellectual Cooperation, taken over by UNESCO after the Second World War – all bodies that worked in favor of the intercountry circulation of people and organizational models (Sapiro, 2009b). At the same time, markets emerged, with borders going far beyond those of the Nation-state (for example, linguistic areas constituted spaces wherein printed works in the lingua franca, English, French,

Spanish, Portuguese, or Arabic could circulate). Bourdieu (2000b) himself analyzed the formation process of a world economic field dominated by multinational companies and characterized, among other things, by delocalizations and capital flows. Moreover, the legal field, strongly linked to the Nation-state, became highly internationalized when its heteronomous pole was put at the service of the market (Dezalay, 1990; on the use of Bourdieuan theory for studying the legal field, see Dezalay and Madsen, 2012). Though the political field remains strongly national, European construction favors the emergence of a European bureaucratic field (Georgakakis, 2012) and of a European legal field, though both are still highly dependent on the Nation-states (Vauchez, 2008). The emergence of more or less autonomized transnational spaces depends on the existence of places of exchange and specific authorities. These entities differentiate fields from markets; examples are international scientific Congresses or the Nobel Prize in literature (Casanova, 1999). In parallel way, the space in which symbolic revolutions are received may circumscribe a transnational field. Temporal lags and the logics of retranslation of issues at stake from one field of reception to another can be regarded as indicators of the autonomy of national fields.

Apart from Brazil, the international reception of the concept of field, beginning in the 1980s, was initially due to literature specialists, in Belgium (Dubois and Durand, 1988), Germany (Jurt, 1992, 1995), Italy (Boschetti, 1985), and Israel (Even-Zohar, 1990). At the same time, the notion was also introduced in Greece and Russia. Used much less frequently in the United States than the concepts of cultural capital and habitus, the concept of field – as Bourdieu theorized it – did not begin to be appropriated by American scholars as a research program until after the sociologist's death in 2002. The concept contributed to the renewal of studies on imperialism and colonialism (Steinmetz, 2008; Go, 2008). In this perspective, colonial states are conceived as *metafields* including state fields within colonies, in which relations of power and competition between different fractions of the field of colonial power coincide in a struggle to define indigenous politics (Steinmetz, 2008). The concept of field is also more and more frequently introduced in the field of international relations (Bigo and Madsen, 2011), where it is used namely in order to think diplomatic relationships such as a *metafield* (Adler-Nissen, 2011). In the sociology of law, a study was carried out on the field of international penal justice, located at the intersection between three transnational fields–interstate relations, defense of Human Rights, and penal justice, which is undergoing internationalization (Dixon and Tenove, 2013).

Organizational Fields and Strategic Action Fields

The concept of field has met with two main theoretical redevelopments more or less inspired by Bourdieu's theory, around the notions of 'organizational fields' and of 'strategic action fields.'

The neoinstitutionalist theory of 'organization fields' developed by Paul DiMaggio and Walter Powell (1983, 1991) aims to show the phenomenon of institutional isomorphism between organizations within the same field. According to DiMaggio and Powell, the processes of rationalization such as Weber described is less dependent on competition and the search for efficiency as on specifically institutional factors. Constraint (via authoritarian means, the legal system, or orders) imitation in situations of uncertainty and normative pressure linked to professionalization are the three mechanisms that favor these fields' homogenization. It is therefore possible to predict this tendency for resemblance based on the type and degree of dependence between organizations within the same field, the degree of uncertainty as regards ties between means and objectives, and the degree of social recruitment of professionals with the same academic training and/or the same engagement with professional bodies. The empirical studies upon which sociologists have formed their analysis are the organizational models used for the production of high-end cultural services, models that appeared in the United States at the end of the nineteenth century (DiMaggio, 1981), and the progressive homogenization of American academic publishing (Coser et al., 1982). DiMaggio also created the notion of 'institutional entrepreneur,' which refers to the foundational figures in emerging fields.

Largely fueled by Bourdieu's field theory, the concept of 'strategic action field' developed by Neil Fligstein and Doug McAdam (2012) combines the neoinstitutionalist approach with collective action theories in order to consider reproduction and change on the mesolevel of social order. From the Bourdieuan conception, Fligstein and McAdam retain the ideas of a field's specific issues at stake, rules of the game, the unequal positions of agents and the link between these unequal positions and agents' vision of the world. However, these strategic action fields are less stable than the fields in Bourdieu's theory; their boundaries shift depending on the definition of the situation and the issues at stake in the field. The fields may be ordered along a continuum based on their degree of consensus. In the case of declared conflicts, struggles are liable to bring about a new order. These struggles are primarily fought between 'incumbents' and 'challengers,' and are regulated by 'governance units' that control a field's functioning and generally tend to conserve the existing power relations in the field. It is possible to recognize here the equivalent of the authorities, the crucial role of which Bourdieu brings to light in fields of cultural production or other types of regulating bodies. Sharing the agonistic conception developed by Bourdieu, the model of strategic action fields more clearly classifies the foundations of collective action between coercion, competition and cooperation, and thus more clearly delineates fields organized hierarchically and wherein different forms of coalition prevail. The question of the relation between individuals and the field, problematized by Bourdieu by means of the concepts of habitus, strategy, and the sense of the game, is considered here in terms of the 'skills' actors possess in order to act in a field. Far from being autarkic, these strategic action fields maintain relations with other fields that differ according to distance/proximity, independence/dependence (in certain cases, interdependence), and the distinction between state and nonstate fields, with the state being considered, as in Bourdieu's theory, as a set of fields (or a *metafield* in Bourdieu's terms). This field environment often plays a major role in change, through, for example, the importation of models from another field. Transformations are frequently provoked by exogenous shocks that provide challengers with new

opportunities, but they require a mobilization process along with use of organizational resources and efficient means of contest. For instance, Rosa Parks' refusal to give up her seat to a white man in a bus in 1955 and her subsequent arrest were not new events in themselves, but civil rights leaders succeeded in turning the episode into an opportunity for mobilization against injustice by convincing black ministers in Montgomery, Alabama, to urge congregants to protest against her arrest. During 'episodes of contention,' one often observes recourse to innovative forms of collective action, as well as a '(re)framing' of the established vision of the world, liable to lead to a new 'institutional settlement.'

The concept of field thus appears to be a heuristic tool for exploring the mesolevel of social activities. While different uses of the concept have been developed in relation with organizational and collective action theories, Bourdieu's field theory continues to function as a research program in different domains and disciplines, raising new questions about colonial and transnational fields, as well as relations between fields.

Fieldwork in Social and Cultural Anthropology

Moshe Shokeid, Tel Aviv University, Tel Aviv, Israel

Abstract

The article presents the origins of the method of fieldwork in European and American anthropology. It introduces the practice of fieldwork – 'participant observation' – as developed in the study of small, remote societies, during the era of colonialism. The article proceeds to discuss later transformations in ethnographic research: moving away from the colonial territories to fieldwork sites in Western industrial societies. The choice of new types of communal and institutional settings in urban and globalized spaces of social life also instigated major changes of methodology and theory in ethnographic projects. These include also a growing awareness of the impact of the researcher's presence during fieldwork, his/her identity, as well as the expansion of the variety of the types of data considered in ethnographic projects.

Origins of a Method

Fieldwork is a term that has been employed for nearly a century by social–cultural anthropologists as a major methodological tool and a profound professional experience that leaves its mark on their lives throughout their careers. It designates a complete concentration on observations in their chosen site of research, for a considerable period of time, usually of no less than 6 months and up to a few years. Originally, this engagement involved a total separation from the researcher's ordinary life and his/her immersion into a remote and an alien social environment. Anthropological fieldwork is known also as the 'ethnographic method.'

The idea of fieldwork owes its origin to the interests of scientists at the turn of the nineteenth century concerning the evolution of the human species, as much as to the expansion of European colonialism that brought under its rule vast territories inhabited by unknown 'exotic' peoples. But no less, that movement coincided with a growing awareness in the United States about the vanishing cultures of Native Americans. The new science of anthropology that intended to satisfy these interests was at its first stages mostly speculative, based on secondary sources of data collected by missioners, traders, colonial administrators, travelers, adventurers, etc. The practice of prefieldwork anthropologists was nicknamed 'armchair anthropology.' Its most celebrated as well as discredited representative remains James Frazer whose monumental work was all based on library material.

The invention of fieldwork as the characteristic method of anthropology, as well as of its corollary aspect of 'participant observations,' has often been attributed to Bronislaw Malinowski, the British–Polish scholar, who is also considered among the founders of the school of functionalism in anthropology. His claim to fame as a fieldworker is based on his long stay, of more than 2 years, during World War I, among the Trobriand islanders of Melanesia. Although he was not the first to employ the method engaging participant observation, nevertheless, his linguistic skills, the meticulous ethnographies he produced, and the introductory chapter on his method of inquiry that opened his most famous work (*Argonauts of the Western Pacific*, 1922) have become the hallmark and quintessential model of fieldwork for almost half a century.

The fieldwork projects carried out by Malinowski, his colleagues, and the later generations of younger anthropologists entailed observations of the minutiae of everyday life in the various domains of social behavior and cultural traditions. In sum, it was supposed to record the totality of the social experience in the studied society. The essence of fieldwork was encapsulated, for example, in the following statements by representatives of three generations in British anthropology:

> This goal is, briefly, to grasp the native's point of view, his relation to life, to realize his vision of his world. (Malinowski, 1922: p. 25)
>
> First, in my estimation, is the point that fieldwork in the empirical mode remains the *sine qua non* both for the testing of theory and, what is more important, for making new discoveries. (Fortes, 1978: p. 24)
>
> 'Good' fieldworkers are those who are prepared to have good 'trips,' that is, suspend as far as possible their own social conditioning in order to have sensory and mental knowledge of what is really happening around and to them. (Turner, 1985: pp. 205–206)

In the United States, the method of ethnographic fieldwork was initiated by Franz Boas and his students most of whom had until World War II concentrated their work in the not too far away reservations of Indian tribes. Their trips to the fields of research had rarely involved a long departure from their ordinary life and work. They were also far more dependent on key informants who provided them with data on specific subjects. Consequently, they were not as deeply engaged in the routine of everyday life of the people they studied. The ethnographies by Alfred Kroeber and Robert Lowie are good examples of the achievements and deficiencies of the tradition of short fieldwork trips and reliance on informants. Margaret Mead, probably the most celebrated among Boas' students, who went to Samoa in a style of research closer to the British tradition (1928), was later seriously criticized for her poor work as a fieldworker. It was mostly since the mid-1940s that American anthropologists have been equally engaged in intensive fieldwork projects away from home. Compared with the British tradition, American anthropologists, since the early stages, have developed a distinctive orientation in their fieldwork projects, more broadly directed toward inquiries of culture and personality (transformed in later years to domains of

experiential, interpretative, and symbolic anthropology, for example, in the works by Clifford Geertz (1973), Turner (1967), and Turner and Bruner (1986)).

The method of fieldwork was adopted in most Western European countries, though in France the interests of leading anthropologists (Lévi-Strauss in particular) were far more concentrated in oral and textual traditions such as tribal myths of creation. They attributed little importance to the ethnographer's experiences *in vivo*. The ethnographic tradition was also adopted outside Europe and the United States (in India in particular).

The Practice of Fieldwork

As a first step in their project, fieldworkers in the Malinowskian tradition have always been acutely aware that they must develop *rapport* and friendly relationships with the people in their chosen field. They are expected to listen attentively, and witness whatever happens around them in the field, without disturbing the natural flow of events. As they consolidate their position with locals, they usually add information through more active modes of communication (such as initiating conversations, interviews, collecting statistical data, taking photographs, etc.), but they are careful not to instigate a flow of information into preconceived patterns of their own making. They invest much of their time recording this material in their notebooks or computers. The bulk of that store accumulates into their most treasured fieldwork product – 'fieldnotes' (to be later transformed into an ethnography). The hallmark of anthropology, fieldwork had also come to differentiate anthropology from sociology. That major difference became more prominent a few decades later when anthropologists were no longer confined to the study of remote Third World societies.

The practice of fieldwork has raised many, as yet not fully resolved, problems of methodology and ethics. Considered a 'method,' it is assumed to maintain a standardized guide for professional behavior, as well as technical rules concerning the collection and recording of data. But throughout the history of anthropology, the craft of fieldwork was practiced mostly by individuals who went on their own to explore new research sites where they confronted conditions and constraints not envisioned by their teachers and colleagues. For many years, the teaching of anthropology in many universities did not include specific courses in methodology. The apprenticeship in anthropology was gained through more informal methods such as a close familiarity with the relevant corpus of ethnographies (and particularly those associated with the candidates' departments, for example, 'The Manchester School'), attending presentations and seminars by colleagues who returned from the field, communication with those who had already gone through the experience, and finally, through the good or bad fortunes of the novices on their arrival in the field and their success in establishing rapport with their native hosts. No surprise, fieldwork had been often described as the major *rite de passage* for students of anthropology. Many anthropologists have been engaged in one major fieldwork project only. But it seems that more ethnographers have gradually become involved in a few fieldwork ventures throughout their career.

Ethnographic work in the various sites of fieldwork, in the early days and today, has been based on an ethos of trust. Anthropologists, mostly engaged in a lone journey, have never been able to implement a procedure of testing the accuracy and truthfulness of fieldnotes reported by colleagues and students. Rarely did fieldworkers choose to return to a field studied already by another ethnographer. The few cases of contested reports have gained much attention, the controversy between Oscar Lewis and Robert Redfield who studied the same community of Tepotzlan, and in particular, Derek Freeman's (1983) refutation of Margaret Mead's observations in Samoa. But long-term research, carried out by anthropologists whose continuing interest and commitment to a particular field has been supported by sufficient funds or easy access, also offered a strategy of verification of observations made at earlier trips.

Although anthropologists have been expected to master the language of the society they studied, that prerequisite was rarely fully achieved. Constraints of time and linguistic skills often impelled them to rely on 'informants' as interpreters until they gained a better command of communication in the native languages. The length of stay in the field was usually determined by budgetary as much as by personal circumstances. But an informal norm of 1 year seems to have dominated mainstream fieldwork projects.

How fieldworkers present their role, and to what extent their subjects comprehend the purpose and consequences of their work, remains an unsolved ethical problem. However, some norms that pertain to a universal code of behavior have been institutionalized at an early stage, such as the disguise of the community studied. More rigorously maintained is the tradition of disguising the identity of individual participants. But no forcing regulations were designed in regard to the rights of privacy in recording and disclosing of intimate information collected during fieldwork. Anthropologists were actually left to make their own decisions concerning ethical issues under the assumption of a deeply felt responsibility toward 'their people.' This dilemma was addressed, for example, by Geertz (1968: p. 157): "A professional commitment to view human affairs analytically is not in opposition to a personal commitment to view them in terms of a particular moral perspective." In any case, fieldworkers were expected to record in their fieldnotes, without censoring, as much as they could remember from their daily observations and conversations.

During many years of practice, however, anthropologists informed their colleagues, also in a more public fashion, about the circumstances they encountered during fieldwork. The early publications had mostly revealed the personal tribulations of individuals in their respective fields (Powdermaker, 1966; Freilich, 1970). But certain specific subjects of methodology had engaged a more rigorous professional treatment. For example, 'the extended case method' (Gluckman, 1958), though mostly a method of ethnographic presentation, suggested a follow-up strategy that stimulated the fieldworker to concentrate his/her observations, thereby revealing the hidden connection between disjoined events. Another theme that gained much attention concerned the various types of informants one might meet at entrance to a new field, and the strategies and precautions one might consider working with them (Casagrande, 1960; Shokeid, 1988). Detailed manuals and reference materials for the various aspects of fieldwork

have gradually developed into books of methodology so long absent (Epstein, 1967; Wax, 1971; Agar, 1996; Ellen, 1984; Shaffir and Stebbins, 1991; and Wolcott, 1999). A more meticulous approach came to fore examining the methods of recording and safekeeping of fieldnotes, the most valuable product of fieldwork (Sanjek, 1990). Also, conferences dedicated to specific methodological issues have become frequent events (such as 'fieldwork at home,' 'long-term research').

Transformations in Fieldwork Research

The idea of fieldwork had gone through immense changes since the days of Malinowski and the generations that established the ethnographic tradition of participant observations in remote, apparently homogeneous societies, clearly identified within territorial and cultural boundaries. The consequences of World War II, the decline of colonialism on the one hand, but the expansion of anthropology in academia on the other, made both the entry and the budgeting of long trips to remote continents an impractical goal for the growing number of students. Instead, many candidates turned their interest to various attractive fields within the borders of their own societies. No doubt, there had been previous successful projects in the United States and Europe of ethnographic studies in fields 'at home' (e.g., the most celebrated work in an Italian lower class Boston neighborhood by Whyte, 1970 [1943]). But these few research endeavors were unusual cases in a tradition that was directed to confront 'other cultures' away from home.

The new search for fields close to home seemed at first to involve only a transfer of sites, such as the study of the apparently clearly defined urban ethnic neighborhoods in the United States (Lewis, 1966; Hannerz, 1969). However, that novelty demanded a change in the style and intensity of participant observation (Plotnicov, 1973). But of more profound consequence, the next change of spatial sites of fieldwork came to also include institutions that offered specific services to permanent or transient populations (for example, Myerhoff's (1978) work in a community center for aged people). That transformation opened the door to a choice of fields that, hitherto, have not been considered suitable for observation (e.g., fieldwork in the scene of gay life by Newton, 1972; Read, 1980; and Shokeid, 1995). In these fields, the fieldworker is often unable to observe the participants throughout a wide spectrum of daily activities. Moreover, in the fields of anonymous participants, the observer's ability to record behavior and communicate with his subjects of research had been very limited in scope (Leap, 1999). These new fields were instrumental in the development of the method and theory of *symbolic interaction* (associated with Erving Goffman's work).

The transformation of methods could also be identified in the choice of problem-oriented ethnographic projects. Even when the relevant site was actually a bounded territorial unit, it engaged a modified strategy of fieldwork (Ginsburg, 1989). But another major change of sites entailed a complete eradication of the bounded spatial characteristics of fieldwork. These unbounded sites included observations of participants in particular occupations (Agar, 1986; Hannerz, 2004), observing cultural performances (Heilman, 1983), as well as observing the members of dispersed social categories (Ortner, 1997). These fields, no longer designed to record the totality of personal and communal life experiences, have been variously defined: *delocalized*, *multisited*, *postcommunity*, *transnational* spaces, and *polymorphous engagements* (Marcus, 1998; Amit, 2000; Shokeid, 2007; Hannerz, 2010).

The ongoing change of the spatial research entities has not necessarily transformed some of the major characteristics of fieldwork. Anthropologists in the new fields continue to initiate their observations mostly as individuals, men or women, engaged in their lone projects. It seems, however, there are less couples involved in these projects, compared with the tendency of married anthropologists to take along their families to the more remote field sites.

In recent years, however, some issues not considered before, concerning the fieldworker's feelings and demeanor, have been openly raised in conferences and edited volumes. Anthropologists preparing for a fieldwork project have never been requested to consult about their personality traits and social capabilities to accommodate what might become stressful field circumstances. But since Malinowski's widow published his personal diaries (1967), revealing the prejudices and the emotional stress experienced in the field by the mythical founder of fieldwork, a more relaxed attitude was gaining place in the professional discourse about fieldworkers' personal problems. This attitude has been closely related to the genre of reflexivity that since the late 1970s gained popularity in ethnographic texts (Rabinow, 1977; Ruby, 1980). The lone fieldworker was no longer perceived through the image of the infallible man or woman but expected to withstand successfully all obstacles in a valiant test of personality that proves he/she is capable of penetrating the social codes of alien cultures in far away territories.

The new fieldwork sites in Western urban societies contributed to that growing awareness and doubts about some long-established taboos that separated fieldworkers from the subjects of their observations (Kulick and Willson, 1995; Lewin and Leap, 1996). The border between the observer and the observed that was naturally upheld in the old fields, where the alien researcher had been conspicuously distinguished (by race and other visible marks of personal characteristics), is no longer easily maintained in many of the new sites of fieldwork. The photographs displayed in many ethnographies of the founding generation, showing them in a landscape of exotic trees and simple huts, posing in the company of minimally clothed natives, have become a symbolic emblem for the changing circumstances of fieldwork.

It is probably an irony that by the end of the twentieth century, a century that gave rise to modern anthropology, fieldwork, its most inventive method and major signifier of professional identity, seems to have lost its incontestable paramount position. Critical views of the validity of positivist methodology, as well as the growing influence of post-modernist currents in cultural studies, are challenging the authority of ethnographic texts based on participant observations (Marcus and Fischer, 1986). These intellectual movements, popular in recent years, inspire and legitimize anthropological projects that are based on other types of data (such as textual, mass media creations, and Internet

connections), which can be collected without the need for fieldwork. It is too early to predict whether the new genre of armchair anthropology will have a more lasting impact on the role of fieldwork and its practitioners.

Abstract

Fieldwork involves a range of methodologies including ethnographic participant observation, in-depth interviews, direct observation of individual or group behavior, or a combination of both qualitative and quantitative approaches. Social scientists conducting fieldwork confront unique ethical dilemmas in the course of implementing their investigations, particularly when researchers are actively engaged with participants in their natural environments. Ethical dilemmas occur when there are conflicts about what is considered to be an appropriate response to a situation involving the investigators, research participants, or the production and use of research materials. A full treatment of these issues is beyond the scope of this article. This article briefly explores ethical issues associated with informed consent, the protection of confidentiality, the development of personal relationships with research participants, involvement in illegal activities, and intervention in ongoing social activities. Finally, a framework for resolving ethical dilemmas in fieldwork is outlined.

Fieldwork involves a range of methodologies including ethnographic participant observation, in-depth interviews, direct observation of individual or group behavior, or a combination of both qualitative and quantitative approaches (Denzin and Lincoln, 1998). Social scientists conducting fieldwork confront unique ethical dilemmas in the course of implementing their investigations, particularly when researchers are actively engaged with participants in their natural environments. Ethical dilemmas occur when there are conflicts about what is considered to be an appropriate response to a situation involving the investigators, research participants, or the production and use of research materials. A full treatment of these issues is beyond the scope of this article. This article briefly explores ethical issues associated with informed consent, the protection of confidentiality, the development of personal relationships with research participants, involvement in illegal activities, and intervention in on-going social activities. Finally, a framework for resolving ethical dilemmas in fieldwork is outlined.

Informed Consent

National and international guidelines for ethical conduct in research with human subjects identify specific requirements for informed consent: the provision of information, comprehension of information, and voluntary participation (Faden and Beauchamp, 1986; Weisstub, 1998). Voluntary participation in research depends upon the individual's ability to understand not just the meaning of the research, but the impact it may have on his or her life. Excessive financial compensation or unrealistic promises may constitute coercion, especially if someone is vulnerable because of social factors such as poverty or ethnic background. Voluntary participation may be inhibited when there are social status and social class differences between fieldworkers and research participants—differences based on gender, age, education, income level, religious affiliation, and ethnic identity. The institutional affiliation of the field researcher may also pose a threat to participants. Additionally, the fluid and unbounded nature of many social science field studies complicates the straightforward approach to informed consent associated with other forms of social science methodologies.

A number of factors influence informed consent in fieldwork—the specific goals of the research, the cultural context of the research project, and communication issues that influence comprehension of information. In international settings, the challenges associated with implementing informed consent in fieldwork are heightened because of language barriers that may inhibit effective communication, particularly regarding the translation of scientific concepts. Misunderstandings and miscommunication about social science research are more likely to occur when fieldworkers and participants speak different languages. Language barriers may be reduced through the use of an interpreter. However, translators must negotiate not only language, but also cultural and contextual factors. Some of the problems associated with interpretation in social science fieldwork include: the inability to translate equivalent expressions easily across languages; paraphrasing that results in omissions or erroneous substitutions of terms; varying levels of comprehension; and the influence of conflicting cultural beliefs and values concerning the meaning and purpose of research.

Differences in beliefs about who has the authority to give permission to participate in research also influence the consent process. Beliefs about personhood, individual autonomy, and decisional capacity are embedded within the social and cultural patterns of family ties and community obligations. In Western industrialized nations, where personal autonomy is emphasized, research participants are expected to make decisions for themselves or through designated surrogates. However, in many non-Western settings, religious or tribal leaders or a person's extended family may play a significant role in decisions concerning research participation. Cultural differences in beliefs about the nature of personhood and the location of decisional authority for consent have been problematic for social science investigators conducting fieldwork in international settings (Levine, 1991). Negotiating informed consent

with designated authorities in non-Western populations requires fieldworkers to move beyond narrow definitions of personhood, autonomy and self-determination. While respect for persons demands cultural sensitivity to local customs, social scientists conducting fieldwork are never authorized to conduct research without regard to potential harm and without attempts to be informative throughout the duration of the study (Levine, 1996). Moreover, although a tribal chief, village elder, or community leader may express approval of a research agenda, sensitivity to cultural customs is secondary to honoring individual choice regarding participation (World Health Organization and the Council for International Organizations of Medical Sciences, 1993).

Informed Consent in Observations of Group Interactions

In fieldwork involving direct observation of group activities, arrangements usually are made prior to initiating the study to inform group members that the fieldworker will be present in the course of routine activities. In closed systems such as a hospital unit, a community center, or other institutional setting, informed consent should be obtained from all those who are at the facility on a regular basis. Individuals who are not present on a regular basis but whose behavior may be observed in public group activities should be alerted to the presence of the fieldworker if it is feasible to do so. In some group observations conducted in the course of fieldwork, it may not be possible or necessary to obtain informed consent from every person present. For example, at informal gatherings such as family or community events, or in public places where individuals interact informally, it would be intrusive for the fieldworker to explain the study to everyone present.

Protection of Confidentiality

Protection of confidentiality and privacy for research participants is an important aspect of fieldwork (Cassell and Jacobs, 1987). Fieldwork in social science investigations often involves the collection of sensitive information concerning an individual's personal life, including information on physical conditions, mental illness, or behavior regarding illegal activities. Individuals or communities could be harmed if information was inadvertently or purposely disclosed. In some cases, information could be used to ostracize or marginalize research participants, particularly if research participants suffer from a stigmatizing illness such as HIV/AIDS, or if they are involved in activities that may be viewed as socially deviant.

Data collection strategies associated with fieldwork require careful attention to the representation of individuals and communities in written transcripts derived from interviews and observations (Fluehr-Lobban, 1991). Descriptive data recorded in field notes, daily logs, or diaries should be entered using a coding system that protects the confidentiality of the research participants. Additionally, field data should also be secured outside of the research setting in order to safeguard the identity of participants. Pseudonyms, rather than the names of participants, must be used in published manuscripts that include case narratives. This gesture, however, will not necessarily protect confidentiality because it may be possible to identify the individuals involved based on the details of the case and the research setting. Nevertheless, at each stage of the research—data collection, data analysis, and data reporting—every effort should be made to protect the privacy of the study participants. In obtaining informed consent, investigators are obliged to advise participants in fieldwork about the methods designed to protect their privacy.

Relationships with Research Participants

Social scientists involved in fieldwork have the opportunity to form close personal relationships with research participants because of the collaborative nature of ethnographic approaches such as participant observation. The development of trust between fieldworkers and the individuals involved in the research enhances the potential for collecting important information relevant to the study. However, in some circumstances, investigators may find themselves in compromising situations because of their personal relationships in the field.

Intimate Relationships

Although it is rarely addressed in the literature (for an exception, see Kulick and Willson, 1995), fieldworkers may become intimately involved with research participants. Sexual relationships with field participants are more likely to occur in the context of extended fieldwork. Traditional anthropological fieldwork—where the investigator may spend months or years in an environment far removed from familiar social networks (often in a different country)—represents the type of setting that contributes to the development of intimate personal relationships with research participants. Despite what some might view as the natural inclination to form a sexual attachment with a close companion, the prevailing opinion among social and behavioral scientists is that sex with participants in the field should be avoided. Sexual relationships between researchers and study participants may diminish the relative objectivity of the investigator.

More problematic is the potential for coercion of socially vulnerable individuals. Moreover, attitudes concerning sexual behavior are socially constructed and the meanings attached to sexual intimacy may vary significantly between the fieldworker's home community and the research setting (Singer et al., 1999). The social complications that can result from a sexual relationship (e.g., jealousy, accusations of infidelity, gossip) jeopardize the integrity of the research and place the investigator at risk for problematic interactions with the broader community.

Illegal Activities

Investigators conducting fieldwork with populations such as illegal immigrants, or with individuals involved in activities such as drug use or the sex trade, may be asked to participate in behavior that is legally questionable. For example, fieldworkers investigating the use of illegal drugs may be asked to share drugs with study participants or to assist in procuring or holding drugs or drug paraphernalia. While some researchers may believe that participation in these types of activities

strengthens the bonds of trust between a fieldworker and research participants and thus increases the likelihood of securing information that is meaningful and necessary to achieve the study goals, there are strong reasons for avoiding participation in illicit or illegal behavior. As with sexual involvement with study participants, engaging in illegal activities seriously threatens the integrity of study findings and places the researcher at risk socially, professionally, and in some cases, physically. Fieldworkers may find themselves targeted for blackmail or other forms of coercion. Additionally, fieldworkers who participate in illegal behavior diminish the potential to secure funding for future research. A full consideration of the ethical dimensions of involvement in illegal activities cannot be explored in this article.

Fieldworker Intervention in Ongoing Social Activities

Questions concerning the intervention of a fieldworker in problematic situations that occur in the course of conducting research are challenging. The fieldworker's decision should be a judgment based on the purpose of the study, the context, and the specific event that occurs. When investigators continually intervene in field situations that are directly related to the issue being investigated, the possibility that their research will have an impact is jeopardized since they would be unable to document the events being studied. For example, fieldwork with injection drug users to investigate HIV risk behavior would be inconclusive if researchers attempted to stop practices known to facilitate the transmission of the virus. The fundamental problem is one of advocacy—when to be an advocate for research participants and when to maintain the more circumscribed role of the investigator (Bosk, 1985). In general, nonintervention is the accepted mode for fieldwork.

Recommendations for Resolving Ethical Dilemmas

Investigators who confront moral dilemmas in the course of conducting fieldwork must consider carefully the full range of issues involved in the problem. A systematic approach to ethical decision-making begins with a robust description of the research dilemma. This would include details about the purpose of the study, the research design, the sponsors of the study, and the individual participants and community involved in the research. The researcher then must consider the cultural and social values represented in the ethical problem. The relevant values of the study participants, the study community, the professional community, and the study sponsors should be outlined. The researcher must determine the principal value conflict. At this point in the process of decision-making, the fieldworker should consider whose values are threatened and who are the most vulnerable to potential harms. This process of reflection facilitates the identification of the key issues involved in the ethical dilemma. When the primary ethical issues are determined, the investigator should outline a full range of strategies and consider the potential risks and benefits associated with each solution. The decision regarding a course of action should maximize respect for the individual and group values identified. The vulnerability of research participants and the communities within which they live should be of paramount importance in resolving the ethical dilemma encountered.

Abstract

The production and distribution of motion pictures occurs throughout the world but since the 1920s has been dominated by giant Hollywood studios. These vast multinational enterprises create films that are presented in virtually every country in the world, frequently capturing a major share of the business despite competition from locally made and distributed motion pictures. Almost continuous technological change has never lessened Hollywood's power, and indeed the innovation of home video extended Hollywood's influence. Marxist critics have long seen this influential cultural industry as a classic example of monopoly capitalism, focusing on how these long-lived corporations devised ways to maintain their power. Neoclassical free market economists, on the other hand, have stressed that Hollywood has long faced entertainment alternatives. Industrial organization economists note that basic forces, such as economies of scale of international distribution, have always enabled Hollywood not only to dominate the world market, but also to set the standard of narrative structured entertainment. Whatever the proper explanation of the maintenance of economic power, filmmakers outside Hollywood long have struggled to find their place in their national cinemas, often requiring the assistance of their governments. Only sporadically have other nation-states—first France, then Italy, Japan, and India—been able to mount a studio system as an alternative.

The production, and distribution of cinema occurs throughout the world but since the 1920s has been dominated by eight or less giant Hollywood studios. These vast multinational enterprises create films that are presented in virtually every country in the world, frequently capturing a major share of the business despite competition from locally made and distributed motion pictures. Almost continuous technological change – led by the Hollywood oligopolists – did not lessen Hollywood's industrial power, and so all other film industries sought to ape Hollywood's continuous success. The coming of sound and color, and the innovations of pay-TV and home video (played on VCRs) simply extended Hollywood's influence, and increased its profits. Analysis of the Hollywood studio system has led to praise or damnation of this omnipresent, inescapable, and highly influential industry.

The Film and Video Industry

A handful of companies have defined the Hollywood film industry, dominating the US and world markets. They have weathered a world war, and a Great Depression, innovated wide screen and color technologies, made peace with television, learned to exploit home video, and were more powerful at the end of the twentieth century than ever before.

The coming of sound solidified control by five studios over the world cinema market: Paramount Pictures, MGM, Twentieth Century Fox, Warner Bros., and RKO. During the 1930s and 1940s by controlling the key cinemas in the downtowns of nearly all major US cities, the 'Big Five' took in nearly all box-office take. Only after they granted their own theaters first-runs, did they then permit smaller, independently owned theaters to scramble for the remaining bookings months, or even years, after a film's premiere.

Paramount represented the most profitable, powerful, and traditional business-like Hollywood company. More than any other member of the Big Five, Paramount relied on its chain of more than 1,000 theaters to maintain its corporate might. Not surprisingly, a former theater operator, Barney Balaban, stood at the top of this corporate colossus, hiring more lawyers and MBAs than movie stars.

Metro-Goldwyn-Mayer (MGM) technically functioned as a successful unit of Loew's, a theater chain concentrated in the Eastern USA. MGM, more than any other studio, relied on the star system, producing films from its massive Culver City, California-based 'factory' of 27 sound stages (for interior shots), and a 168-acre back lot (for outdoor scenes).

Twentieth Century Fox ranked behind Paramount and MGM with neither as large a theater chain or studio facility. Studio boss Darryl F. Zanuck used what he had to authoritatively produce films for world distribution. His decisions were final, frequently bellowing to all subordinates: 'Don't say yes until I've finished talking!'

Warner Bros. represented the only family-run operation among the major movie studios, with eldest brother Harry as President, middle brother Abe supervising worldwide distribution, and baby brother Jack heading studio production. The innovation of sound pushed Warners into the Big Five, yet financially the company struggled through the 1930s and 1940s.

Radio-Keith-Orpheum (RKO) was formed so that radio's RCA could sell its sound equipment to Keith–Orpheum theaters. While the studio created many memorable films – such as *Citizen Kane* and the Astaire–Rogers musicals – RKO's only regular profitability came from the distribution of Disney animation. TV killed RKO.

The Big Five tolerated some competition – from Universal Pictures, Columbia Pictures, and United Artists – as the 'Little Three' depended on the Big Five for access to the top theaters in the USA. The suburbanization of the US, and the coming of television allowed Universal, Columbia, and United Artists to prosper because the advantage of owning theaters disappeared

because of antitrust action by the US government. The former Big Five, save RKO, tried to re-invent themselves.

Warner Bros. began its transition into what became Time Warner when in 1956 the founding brothers sold out, and a series of new owners embraced television production. In 1969, Kinney National Services, a New York conglomerate, purchased Warners, and Steven Ross, son-in-law of Kinney's founder, began to fashion the modern Hollywood-based prototypical multinational media conglomerate. In 1989 Ross merged Warner with Time, and the largest media company in the world was created. A decade later AOL took control.

Paramount stubbornly hung on until 1966 when Charles Bluhdorn's Gulf+Western Industries conglomerate, after a 2-year battle, took over. Through the 1970s and 1980s the 'new' Paramount thrived as part of a classic conglomerate, but in another 2-year struggle, was taken over in 1993 by another media conglomerate, Sumner Redstone's Viacom, Inc.

Twentieth Century Fox began its reinvention in 1956 when longtime studio boss Darryl F. Zanuck resigned. His replacements struggled, but did lead the way to licensing feature films to major television networks. NBC's 'Saturday Night at the Movies' began TV's showcasing of feature films. The surprise hit *Star Wars* (1977) moved Fox to the top of the Hollywood studio hierarchy, and within a decade led to the studio's purchase by Australian media mogul Rupert Murdoch. From the Fox studio base, Murdoch created the Fox TV network.

MGM never was able to reinvent itself, even with its merger with United Artists. The two other members of the Little Three did far better. Columbia went through several ownership changes (including during the 1980s when Coca-Cola owned it), but it was not until 1989 that stability came when Japanese electronics giant Sony purchased Columbia. During the 1990s Sony never was able to exploit its Hollywood studio to sell more VCRs, but did learn to create vast profits.

Universal also struggled until 1962 when the MCA talent agency acquired it. Thereafter, under Lew Wasserman, Universal ascended to the top of Hollywood movie and television studio hierarchy as Wasserman innovated the made-for-TV movie, and the modern film blockbuster – *Jaws* (1975). Wasserman retired in the early 1990s, and in 1995 Canadian liquor giant Seagram took control.

Disney joined Warners, Paramount, Fox, Sony, and Universal to form the 'Big Six' of the 1990s. Beginning in 1984, Michael Eisner leveraged Disney's weak position into major studio status, a significant change in an industry with so much long-term stability. Indeed, how had this small number of companies survived and thrived for so long – with no real newcomers joining their ranks?

First, even with all the social technological and industrial changes, the major companies alone continued to be able to distribute films around the world. At considerable expense, all maintained offices not only in the USA, but in every region of the world. In most countries around the world, owners of theater chains knew the Hollywood majors alone could continuously deliver popular films, and so even theater owners outside the USA preferred Hollywood films to native productions. The Hollywood studios' record at the box office satisfied theater owners – a conservative lot with most of their assets invested in real estate. Economies of scale prevented rivals from building and maintaining equal world distribution networks.

Second, modern Hollywood fashioned the blockbuster strategy to turn television into a friend, not a foe. Through the final quarter of the twentieth century, the Hollywood oligopoly learned to generate profits from creations that premiered with blitz TV advertising, which in turn was married to a multirevenue generating machine to sell musical sound tracks, novelizations of the stories, 'action figures' from movie characters, and endless sales on video. Each movie aspired theatrically to become a smash hit because if it succeeded then the feature turned into a 'product line,' designed to fill all entertainment needs and desires from toys to theme park rides to campaigns to sell more McDonald hamburgers.

The blockbuster strategy in turn led to ever escalating costs of production so it became more difficult for rivals to join the exclusive Hollywood club. By the close of the twentieth century the average Hollywood feature cost in excess of $50 million to produce, and half again that amount to publicize. *Titanic* doubled those average cost figures, but then earned in excess of $2 billion in revenues. Potential filmmakers knew that if they ever aspired to have a world audience see their creation and to attain undreamed of wealth, they needed to be 'green lighted' by one of the Hollywood major studios.

Alone, Hollywood could keep the revenues flowing year after year – particularly from home video. While theaters still premiered new films, it was 'downstream' on video where the bulk of the monies were generated. The theater functioned as the 'voting booth' where hits were made, and necessary publicity generated. But once the film had fully milked the box-office it went into release on pay-TV and home video that created more than two-thirds – in the long run – of the average film's revenues. Hollywood executives carefully planned – in classic price discrimination fashion – to drain all possible revenues from each of these release venues, only releasing it to home video when they reasoned all the revenues from theatrical and then pay-TV had been procured. Each window in this sequence was an exclusive; a new window opened only when all value of the previous window had been captured. This exploitation of video represented Hollywood's newest advantage in the film industry.

The Rest of the World

While the Hollywood majors maintained their economic power and influence, filmmakers outside Hollywood long struggled to find their place in their national cinemas, often requiring the assistance of their governments. Only sporadically have large nation-states – France, Italy, Japan, and India in particular – been able to mount a studio system as an alternative and serious rival to Hollywood in their own countries, let alone elsewhere.

Globally, only in the rare nation does Hollywood not capture more than half the business. The Hollywood majors maintain offices around the globe, where their representatives maintain constant contact with the heads of the dominant theater chains, pay-TV outlets, and home video retailers. Hollywood's regular production of hit films provides a strong incentive for foreign theater, pay-TV, and home video

companies to consistently deal with them rather than take a flyer with some new company – even a native company.

But other nations did try. During the 1920s European nation-states – led by the United Kingdom, France, and Germany – sought to build their own studio systems, and were successful for short periods of time, until their leading filmmakers left for Hollywood. During the 1920s, the new Soviet Union tried to build an alternative national cinema industry under Communism. The 1930s ended these experiments. At the close of World War II, the focus shifted to state sponsored television, but still in Japan and India studio systems did succeed, even while conceding Hollywood a vast share of the monies paid for cinema attendance.

After the advent of the blockbuster, it became harder for foreign governments to subsidize a native cinema industry. Most chose to focus on television instead. But Germany and Australia, for example, did for a time in the 1980s create enough different types of popular productions long enough to be discovered as the latest 'new wave.' Japan had long had a studio system, but the coming of television and the takeover of Hollywood studios by Sony, and temporarily, Matsushita, ended the importance of that native industry. But India, for example, was still able to maintain native popular cinema, complete with a star system and defined genres like Hollywood. But these films were intended for domestic consumption, with minimal export possibilities. Community viewing in cities and poor areas alike still flourished.

Hollywood has long maintained an influential trade association – the Motion Picture Association of America noted for its ratings of films, but far more influential around the world for lobbying to smooth the way for international distribution. The MPPA lobbied the US State Department to keep cinema trade 'free' to permit the Hollywood oligopoly to continue pulling billions in revenue from the foreign [read: non-US] market. Foreign governments, on the other hand, resented US pressure, and formally and informally sought to protect the national film industries, and their cultural integrity and identity.

Industrial Analysis

The common thread of Hollywood power and influence, and its growing presence around the world, have led to much analysis of the Hollywood film industry. Three different interpretations have dominated.

Marxist Industry Analysis

Marxist critics have long seen this influential cultural industry as a classic example of monopoly capitalism, focusing on how these long lived corporations colluded to devise ways to maintain their power and cultural imperialism. While Wall Street celebrated Twentieth Century Fox and Paramount's co-financing of *Titanic*, Marxist critics would see this as yet another example of studios working together – not competing – to maximize profit. Since there were at most eight players, they did not have to worry about going out of business, but simply seeking how much their exploit and keep in profits.

The long-term propensity toward concentration of ownership, endemic to monopoly capitalism, was simply exemplified by the Hollywood motion picture industry. That is what history should teach us, and that is how Hollywood has behaved even in the face of new technologies. Marxists focus on the expansion of giant corporations and the spread of their influence to television, music, toys, theme parks, and other entertainments. Market concentration and anticompetitive behavior describe the operation and ownership of the Hollywood movie industry.

Marxist industry analysis usually focuses on international distribution, seeing the trend toward globalization as evidence of cultural and economic imperialism. While Hollywood publicity focuses on the production of films – its stars, stories, and special effects – international distribution has always been a key to corporate longevity. No other national film industry has been ever been so far-reaching, endangering indigenous, nonprofit seeking culture. They correctly emphasize that Hollywood taught the mass culture businesses to focus on and exploit the advantages of globalizing as seen in the work of Wasko (1994) and Guback (1969).

Neoclassical Industry Analysis

Neoclassical economists emphasize that movies face competition from all forms of mass culture. While there are and have been a few very powerful studios, consumer sovereignty means that no Hollywood company can ever force a customer to pay to see a film – even *Titanic*. These analysts focus on the forces and interplay of supply and demand, seeing the movie theater as a classic voting booth, where top grossers win and unpopular films are pulled almost immediately. They stress that there is a great deal of product diversity that permeates the entire landscape of the mass media. This is why genres – from science fiction to westerns, from dramas to comedies – ebb and flow in relative popularity. With the rise of the VCR, for example, the choice of titles to rent or buy needs to measured in the thousands. Like the Marxists who come to their analysis with a predetermined anticapitalist assumption, these neoclassical analysts enter the debate with a procapitalism assumption as seen in the work of Litman (1998).

Industrial Organization Analysis

Industrial organization economists start with neither pro- or anticapitalistic assumptions, and instead seek first to define 'who owns the media,' then analyze what economic conduct emerges from that industrial structure, then detail how the industry performs given specified criteria, and finally recommend possible public policy corrections to make the industry do 'better.' Industrial organization economists have long recognized the host of advantages that enabled them to maintain their considerable economic power and keep out the competition.

For example, cross-subsidization enabled a Hollywood corporation – with interests in a number of media markets – to extract profits from a thriving area to prop up another less financially successful area. Single-line corporations do not have this luxury and so aspiring single-line Hollywood operations invariably fail as Gomery (1986) discusses.

Or, to take another example, reciprocity enables a diversified member of the Hollywood major studios to choose to

whom they will sell and then only deal with those companies that cooperate with other units of the media conglomerate. For example, Universal Pictures might not sell movies to Time Warner's HBO unless Time Warner's cable franchises book Universal's (partially owned) USA television network.

Horizontally, year after year, the Hollywood oligopoly has generated considerable profits from a wide spectrum of mass-media enterprises, including theme parks, music, and television production. There is no such thing as a single-line major movie company. The major Hollywood companies also control the process of production and distribution – as they long have – but also more and more of the increasing avenues of presentation, from pay-per-view channels to home video to digital home viewings.

Abstract

Genre is a concept used in film studies and film theory to describe similarities between groups of films based on aesthetic or broader social, institutional, cultural, and psychological aspects. Film genre shares similarities in form and style, theme, and communicative function. A film genre is thus based on a set of conventions that influence both the production of individual works within that genre and audience expectations and experiences. Genres are used by industry in the production and marketing of films, by film analysts and critics in historic analysis of film, and as a framework for audiences in the selection and experience of films.

Main Tendencies in the Study of Film Genres

The concept of genre has been important since the beginning of the history of film, as a category for the industry and thus for the production, marketing, and distribution of films; for film critics and the academic, aesthetic, historical, and theoretical analysis of film; and for audiences as a framework for the selection and experience of films. The study of film genres is therefore placed in a triangular structure relating to the institutional, social, and cultural context of films; to the aesthetic, formal, thematic, and stylistic dimensions; and to audiences and reception understood both in an empirical social and psychological sense.

The development of the study of film genre from classical to modern film theory have shifted between focus on different aspects of this triangular structure. Studies of particular film genres, e.g., the Western or the family melodrama, may stress the social and cultural aspects of genre, as ideological or ritual expressions of American history, values, and mythology, or as part of the Hollywood studio system and the institutional development of production norms (Schatz, 1981). Or studies may stress the formal, narrative, visual, iconographic, and thematic structure of particular groups of films in order to find similarities and variations and historical changes and developments (Staiger, 1995; Bordwell et al., 1985). But studies of genre have also focused on psychological aspects of genre such as gender and the imaginary, using Freudian, Lacanian, and feminist terminology (Mulvey, 1975) or, as it has been the case in recent thinking about genre, from a cognitive and emotional theory of basic prototypes of film genres (Grodal, 2009). Many theories of genre do not stress just one part of the triangle but clearly indicate that genres are unstable and fuzzy categories. Rather than defining film genres as sharp, distinctive, and essential categories, modern genre theory tends to define genres as prototypes, and to see the establishing of genres as processes related to institution, text, and audience and historical changes.

Auteur and Genre

Although film genres are found as categories from the beginning of film history, used by both production companies and film critics, the systematic theoretical and historical reflections on film genres were developed in the 1950s as European auteur theory met US genre films (Fowler, 2002). The early theories of film were often very strongly tied to a more individualized and aesthetic understanding of film as art, and therefore often viewed mainstream cinema and genres as commercially dominated formulas, that did not allow artistic freedom and innovation for the auteur. But although this discussion is often repeated even today, film genre theory in general has explicitly questioned this normative division between an industrialized product and mainstream cinema, on the one hand, and film art and the auteur concept, on the other.

In the 1950s, French critics centered around *Cahiers du Cinéma* and the New Wave stressed the variations and auteurism of classical genre films in their writings on classical Hollywood cinema. Bazin, despite his central role in the formulating of a realist film theory and an auteur theory, was also engaged in describing the special qualities of classical US genre films, such as the Western. In his two seminal articles (Bazin, 1971a,b) published in French in 1953 and 1954, he discussed the Western and especially John Ford's Westerns as US film art *par excellence*. In these articles, Bazin saw the Western as a visual and narrative embodiment of American history and myths, and in his definition of what constitutes a genre, he focused on both thematic elements and elements of cinematic technique and style, narrative strucand *mise-en-scène*. He also initiated later discussions on the historical transformation of the Western, defining both its pure classical forms and newer forms, which he called 'superwesterns' and 'novelistic Westerns.'

Bazin's articles mark a transition from a normative aesthetic notion of genre films as just degraded, commercialized, and industrialized art. He combined auteur perspectives and genre perspectives into a more general aesthetic and cultural perspective on all forms of film. This was also the intention behind a number of later US contributions to the general understanding and reevaluation of US film genres. Braudy (1976) not only explicitly criticized the division between film as art and film genres, but also claimed that mainstream genres can express broader cultural, social, and aesthetic values than classical works of art can. Buscombe ([1970]1995) takes a broad discussion of literary genre theory as his starting point and specifically uses Wellek and Warren's distinction in *Theory of Literature* ([1949]1956) between 'outer form' and 'inner

form' and their cinematic equivalents, thus opening a more structural and aesthetic specification of genre definition.

Semiotics and the Ritual and Ideological Turn

The move from auteur to genre from the late 1960s, was sustained and further developed through the influence of semiotics, structural anthropology, and literary genre theory to a broader ritual and ideological approach to the study of film and film genres. The ritual approach involved both a more systematic analysis of cinematic texts and a form of institutionalized practice expressing and negotiating fundamental cultural values. The ideological perspective involved a critical study of cinema and cinematic genres and the reproduction of dominant forms of ideology from sociological, Marxist, Freudian, and feminist perspectives. The two approaches do not necessarily exclude each other but in the ritual approach there is a tendency to see the relation between genre and audience as one of negotiation and exchange, whereas the ideological perspective more often stresses the principle of dominance.

In Cawelti's broad ritual study of popular literature and film (Cawelti, 1976) and in Wright's classical ritual and structural analysis of the Western (Wright, 1975), genres are seen as fundamental story types that represent and embody cultural images and myths with both universal and historical elements, and which are recognized by the audience. Genres and the act of genre reading balance between mimesis and escapism. Cawelti's idea is that genre formulas work because they are able to express and negotiate historical conflicts and mental and cultural oppositions and contradictions in a way that is accepted, understood, and appreciated by a large audience, not just dominated by ideology. He rejects deterministic theories in favor of symbolic or reflective theories, where assimilation, negotiation, and change take place but without denying that formula stories reflect and affirm dominant forms of thought and attitudes.

Cawelti defines five universal story types that can be used and combined in different ways: adventure, romance, mystery, melodrama, and stories of alien beings and states. In Schatz's (1981) study of classical Hollywood genres he talks about genres in a fundamental semiotic way in which he sees "film genre as a specific grammar or system of rules of expression and construction and the individual genre film as a manifestation of these rules" (Schatz, 1981: p. 19). Basic film genres form the *langue* and individual genre films form the *parole* of genre filmmaking and film language, and he defines the grammar in terms of a genre's iconography, characters, settings, and plot structure. Shatz's analysis is a study of some of the most stable film genres in the classical Hollywood system, the individual films, and the directors, but he also points to two very basic types of supergenres: genres of order (Western, gangster, detective) and genres of integration (musical, screwball comedy, family melodrama) with two very different narrative strategies, settings, types of hero, and solution models of conflicts that either express violent elimination and male dominance or emotional, familial integration, and couple or female orientation.

Shatz's approach points to forms of genre analysis also addressed in the more ideological and feminist genre theories developed at the same time, but with a background in French film semiotics or the influential UK journal *Screen*. One of the seminal articles articulating the ideological approach is Comolli et al. ([1969]1992) article, printed originally in *Cahiers du Cinema* and in English in *Screen* (1972). Every film is political and ideological, they state, in so far as no film or filmmaker can escape the commodity form and the capitalist economy. According to Comolli and Narboni, filmmaking at large is nothing but an expression of the prevailing ideology, which is working behind the back of both the filmmaker and the audience. But the article also defines a kind of ideological genre taxonomy, in which films are defined in relation to whether and how they try to oppose the dominant ideology. Among the seven genres defined are: the majority of films, which are just unconscious instruments of ideology; films that have an explicit critical content and or/form; films that have an ambiguous secret message and form; and films like documentary films, that are seen as only illusionary breaks with the dominant ideology.

Ideological genre analysis found dominance of ideology disguised behind classical realism or inscribed in the apparatus of cinema and therefore viewed the audience as rather passive. However, ideological analysis did look for both a counter-cinema and counterstrategies to the dominance of ideology in genre film and mainstream cinema. But whereas the ritual approach saw qualities in the mainstream film and its relation to the audience on a more direct level, the ideological approach often investigated ambiguities and contradictions in genre films dominated by ideology. Writers belonging to the ideological and semiotic project (e.g., Wood, [1977]1995; Klinger, [1984]1995) therefore also found elements of artistic personality still visible in genre films and often described subversion of the dominant tendencies in mainstream film.

Gender and Genre

The story of genre theory and gender starts with the feminist project based on the ideological and Freudian–Lacanian-inspired genre theory that sought to find the dominant. Mulvey's ([1975]1992) much quoted essay combined elements from all aspects of the ideological genre theory, but with the aim of demonstrating the male dominance of the feminine in mainstream Hollywood. She pointed to the male gaze and the feminine characters as the looked upon object and she also described the asymmetric relation of active/passive roles. But Mulvey's article did not just open the feminist critique of male dominance, but also the demand for another aesthetic, a feminist counter-cinema. Eventually, it also led to the investigation of subversive female readings of classical genre films, most notably 'women's films,' e.g., melodrama or film noir as it is very broadly demonstrated in Gledhill's (1987) anthology on melodrama and women's films and Kaplan's ([1978]1998) on women and film noir, in which prominent feminist film genre critics, e.g., Mary Ann Doane, Tania Modleski, and Annette Kuhn, figure. Later feminist writers have directly entered more action-oriented and excessive 'body genres,' such as Williams studying pornography, horror, and melodrama (Williams, 1989) or Clover's (1992) thorough study of the horror genre. And just as feminist criticism has opened toward seemingly more

'masculine genres,' gender studies of film genres have also included studies of gay and lesbian films or gay and lesbian aspects of mainstream genre films (Davies, 2008; Griffith, 2009).

Genre, Reception, and History

In literary genre theory Todorov (Todorov, [1970]1975) made a distinction between theoretical and historical genres. Theoretical genres are defined in more general terms by criticism and theory and historical genres are defined as genres actively used and recognized by critics and readers. This distinction is a starting point for Neale's (1980, [1990]1995) and Altman's ([1984]1995, 1999) contributions to a genre theory. Neale (1980) represents screen theory that combines ideological and semiotic–aesthetic aspects. But he expands the concept of genre to a very multifaceted process. Genres are both social and textual institutions and, according to Neale, they work to create a coherence and narrative closure, which positions the viewer safely inside a well-known structure: "a genre is, simultaneously, a coherent and systematic body of film texts, and a coherent and systematic set of expectations" (Neale, 1980: p. 37). Altman ([1984]1995) also clearly continues the semiotic project of genre definition, but at the same time seeks a merging of the ritual and ideological approach and the more general description of genres as a grammar and language. His suggestion in the article is thus to combine the semantic approach to genres, defining its 'building blocks,' and a syntactic approach defining the actual structures in which the semantic elements are placed. But at the same time he argues for a stronger historical complexity in the study of genres and for a stronger emphasis on the study of genres in historical contexts and to actual interpretative communities.

This line of argument focusing on reception and the historical process of 'genrification,' and genre as a kind of 'game' between critics, producers, and audiences in a concrete historical process, is strongly underlined in Neale ([1990] 1995) and Altman (1999). Taking some historical examples of how different early film genres were defined in industrial and critical terms and how long it took for well-established genres to stabilize as both institutional and audience categories, Neale argues for genre studies with more real historical integrity, actually studying the discourses on genre used in a historical context, rather than only constituting general, theoretical genre concepts. Along the same lines, Altman focuses very much on the unstable and fuzzy nature of genres and the differences in audiences' readings of individual genres and individual films. He adds a pragmatic dimension to his earlier semantic–syntactic dimensions to include the user-contexts aspect. So key terms in this reception-oriented historicizing of film genre theory are different readings, multiple users, and conflicting understandings of genres, instead of genres understood as relatively stable categories based on both general textual similarities and a social and cultural contract or common understanding.

Cognition, Emotion, and Genre

A move in the opposite direction back to a more general definition of genres can be found in the strong new trend toward cognitive and pragmatic studies of genres from the 1990s and on. The earlier semiotic and ritual sociocultural approach to genres defined dominant structures based on more general patterns of mental, generic procedures, that partly explain why mainstream genres are so strong and dominant. This point of view was based on structural arguments that were not very firmly anchored in a psychological dimension. Cognitive-pragmatic genre studies also define very basic patterns and schemata in our active construction of narrative forms and basic generic formulas. But the cognitive-emotional theories focus on more internal psychological dimensions, but do not exclude a pragmatic-historical dimension, since all such mental aspects of communication are situated and embodied in a specific historical and communicative situation. The cognitive-emotional genre theory also opposes the dominant Freudian, Lacanian, or Jungian-inspired psychology in the Screen tradition of genre studies. Important contributions to this new cognitive-emotional genre theory is Bordwell's (1985) description of different narrative prototypes and the way they cue the spectator and Carroll's studies of horror (1990) and his later article on emotion and genre (Carroll, 1999), in which melodrama, horror, and suspense are described from a cognitive-emotional perspective.

But the most ambitious attempt to formulate a cognitive and emotional theory of genre is that of Grodal (1997, 2009). In his book *Moving Pictures* (1997) Grodal defines a new typology of very basic genres based on the viewer's active–passive relation with the film, the kind of distanciation or identification involved, and the typical moods and emotional responses activated during viewing: associative lyricism, canonical narratives of action, obsessional paratelic fictions, melodramas, horror, schizoid fictions, comedy, and metafiction. Behind these basic forms we then find a number of more concrete, historical subgenres. The basic assumption of the book is that genres of visual fiction are mental structures that to a large degree are modeled on the basis of a simulated reality of actions and emotions to which we react with much the same experiences and capacities as in real-life experiences. The book thus argues that many of the fundamental structures of film experience are based on embodied emotional and cognitive patterns that interact with the concrete social and historical context of audiences.

In his first book Grodal describes both the typical embodied flow, during the experience of visual fiction with reference to cognitive-emotional psychology, and the reason for the strength and popularity of the prototypical genres of visual fiction and their relation to different mental and emotional activities and experiences. Grodal's book is, of course, not strongly oriented toward the cultural and historical aspects of moving images, but there is no essential opposition between a cultural, historical, and stylistic approach to visual fictions and Grodal's position, as long as one realizes that certain aspects of the experience and processing of moving images cannot be described as culturally constructed in any short-term sense.

Further cognitive studies of film genres have been developed by Murray Smith (1995) in a study of how we engage with characters in typical film genres and a broad representation of theories and analysis of film genres, cognition, and emotions can be found in Plantinga and Smiths (1999). Carl Plantinga (2009) takes up the aspect of audience in cognitive

film theory in an attempt to define the universality of the global experience of film genres. Finally, Grodal (2009) develops his basic theory into a more developed model of film experience (PECMA model) and situates it in both modern neurology and evolution theory.

Film and Genres

How many film genres are there and how do we define them and distinguish one genre from another? This is one of the basic questions raised by film genre theory, and this is also the question raised in more concrete, historical analysis of particular film genres and their development. Theoretically there are at one end theories that try to define genres as relatively stable and accepted narrative, stylistic, and thematic structures that transcend individual films and clearly influence and determine both production and audience response; at the other there are theories that stress the unstable nature of genres and the fuzziness of genre categories. Some theories argue for few and very basic generic prototypes with a variety of possible subgenres, that may vary and change historically, whereas practical criticism and the history of film genre categories often show that you can construct genres on the basis of many criteria, for instance, on content and dominant type of narrative action (war films, porno films), on specific stylistic features (film noir, musicals, animated films), on the basis of the expected audience (women's films, children's films), on the basis of emotional response (comedy, melodrama), etc.

Although genres are often related very clearly to the dominance of US cinema worldwide, national variations of genres are also very important and often have more universal influence, e.g., the Asian martial arts films or the British heritage film or costume drama. But although historical, national, and other variations are very common and the number of actual genres defined in some critical context is probably very large, then some basic narrative modes and generic fomulas are stronger and more permanent and universal than others.

Basic Film Forms and Universal Formulas

Kracauer (1960) defined two basic types of film: narrative films (story films), and nonnarrative films (nonstory films), which he divided into 'films of fact' and experimental/avant-garde films. He considered narrative film to be the most important and basic form. In a similar way Williams (1984) has suggested that before we talk about specific subgenres, we should perhaps talk about only three, very basic or principal film forms: narrative film, avant-garde/experimental film, and documentary film. This division is also supported by Bordwell's (1985) division of films belonging to the more canonical, classical narration, which dominates both Hollywood mainstream formats and national European mainstream films; art cinema narration with its more fragmented and less linear models of narration found in, for instance, European neorealism, New Wave cinema, and modernist and postmodern films; and finally nonnarrative forms such as documentary. All three forms have very distinct institutional backgrounds and are normally very easily recognized by the general audience, because distribution and indexing of art cinema, for example, is linked to special cinemas, festivals, and a special critical discourse, and documentary films have a totally separate distribution and are indexed much more for their special reference to reality.

Classical Hollywood and Beyond

Very often the classical Hollywood genres form the basis of what is generally understood as the fundamental genres and these would most typically include melodrama, comedy, action–adventure, science fiction, horror, Western, film noir, crime genres, and musical. But each of these categories has subcategories, such as the crime genre, which is often further divided into gangster films, thrillers, hard-boiled detective films, spy films, police films, etc. A popular Internet site like the Internet movie database lists no less than 21 fiction film genres, mostly based on what the films are about, but also with some style-oriented or audience-defined categories: action and adventure. Among the first are action, adventure, mystery, war films, or historical films. More style-oriented categories are animation, film noir, or musical and among the more audience-based categories we find family films. Neither the historical, critical, nor the popular taxonomy of genres are defined in very rigid and stable forms, although some basic forms are clearly present. As indicated in the ritual approach, the cognitive approach, and in most studies of the classical Hollywood system, it is however possible to define a number of more general generic forms and prototypes, which then often have different subforms and furthermore can change and vary historically.

Several models of typical historical developments of genres have been suggested in film genre theory. Neale ([1990]1995), for instance, discusses the evolutionary model, used by Schatz (1981). In this model genres move from an experimental stage to a classical stage and to stages of more opaque, baroque, ironic, or even metatextual modes in which the basic formula elements are so familiar that directors and audiences have a more playful and reflexive relation with them. Neale points to another model in which genres occupy shifting positions as dominant, and run through phases of canonization, automation, and reshuffling. In recent theories on genre mixing and intertextuality it is furthermore often indicated that it is an increasingly common strategy by both the producer and the director to try to mix genres, to have maximum audience effect, and that furthermore the general audience today is much more used to genre mixing and intertextual and metatextual elements even in mainstream films.

Nonfiction Films and Genre

Many theories and discussions of film genres relate mainly to fictional film; however, both nonfiction film genres and the distinction between fiction and nonfiction are very important for the understanding of the fundamental film genres. Historically, the term documentary was defined by John Grierson in 1926 as "creative treatment of actuality." This definition points to the fact that documentary films, like all nonfiction genres, have a special and more direct reference to reality than even the most realistic fictional film, but that on the other hand all documentary films are also a product of rhetorical and aesthetic

choices. Plantinga (1997) gives a cognitive and pragmatic definition of the distinction between nonfiction and fiction: Nonfiction is related to those discourses that make explicit claims about reality and fiction to discourses that do not, a distinction between an assertive and a fictional mode, in which the spectator treats the reference from text to reality in two fundamentally different ways. This distinction between two modes is imbedded in our cognitive framework and is related to the distinction between a play mode and a reality mode.

Historically, aesthetically, and rhetorically the documentary film has developed many different ways of representing and talking about reality. Barnouw (1993) uses different communicative roles to define different rhetorical purposes in documentary: explorer, reporter, advocate, poet, promoter, and observer. Renov (1993) in his theorizing about documentary forms makes a distinction between four fundamental functions of documentary films: to record, reveal, and preserve; to persuade or promote; to analyze and interrogate; and to express. Combinations of each of these communicative roles or purposes of course result in different subgenres of documentary.

Documentary genre theory offers several ways of defining the basic genres, but one of the most widely cited is Nichols's (1991) definition of four fundamental modes of representation: *the expository documentary* (with direct address to the viewer, often through authoritative voice-over and based on explicit arguments); *the observational documentary* (often based on simply edited visual observation and people expressing views in their observed reality, but without explicit commentary); *the interactive documentary* (based on a more active intervention and interviewing into reality, but still without an authoritative voice and comment); and *the reflexive documentary* (with a dominance of more self-reflexive and poetic strategies foregrounding the film's own strategy and relation to reality). Bondebjerg (2014a,b) defines four basic modes of documentary using both cognitive and pragmatic theory: the authoritative mode, the observational mode, the dramatized mode, and the poetic reflexive mode. If these modes can be taken as basic prototypes, then of course different subgenres can mix these modes and rhetorical strategies and it should also be added that mixing of fictional forms and documentary forms also has a long history. Docudrama and drama documentary or even more complicated fact–fiction formats have developed strongly in recent film and TV culture adding to the aesthetic and rhetorical variations of documentary forms or 'faked' documentary forms (Rosenthal, 1999).

Film History

Charles O'Brien, Film Studies/School for Studies in Art and Culture, Carleton University, Ottawa, ON, Canada

Abstract

Film history has been an established field of study within higher education since the 1980s at least, defined by specialized journals, professional organizations, and conferences. Indicating film history's evolved condition is the extent to which film scholars have begun writing the history of their field of study. Each year, new discoveries stimulate revision of established scholarship just as they underline the incompleteness of the historical record, and hence the certainty that the study of film history will remain a work-in-progress.

As the art of film enters its second century, film historians not only encounter a longer and more heterogeneous film-historical past but do so from within contexts unimaginable during the 1930s, when the first wave of book-length film histories appeared. Film history has been an established field of study within higher education since the 1980s at least, with specialized journals, professional organizations, and conferences. Indicating film history's evolved condition is the extent to which film scholars have begun writing the history of their field of study (Polan, 2007; Grieveson and Wasson, 2008).

Academia's perpetual search for new objects of study, together with the ongoing discovery and restoration of lost films, has enabled a fundamental rethinking of key periods of film history. Foremost is the early cinema that had preceded the formation of Hollywood cinema, and which has been the focus of considerable research since the late 1970s (Abel, 2010; Grieveson and Kramer, 2004). Much of this research has concerned not only the production of films but their exhibition and critical reception, too, and it has entailed a far-reaching reinterpretation of the period. More recently, films produced outside of film history's familiar research domains of Western Europe and the United States have become a focus of study (Hill and Church Gibson, 2000), as in the studies of Bollywood cinema that have proliferated since 2000. Moreover, scholars are investigating not only live-action feature films but also various shots, including films screened in hospitals, schools, prisons, and other noncommercial venues. Animation, long a marginal area of study for film historians, is now receiving new attention in light of current changes in cinema linked to digital image making. New interpretations of film history are certain to occur as films continue to be found, identified, reconstructed, and made available to scholars. As new case studies accumulate, it is questionable whether world cinema can be said to have a history, if the term history is understood to imply a single narrative that might encompass the heterogeneity of the world's films and cinema practices.

Film as Art and Industry

Critics have often distinguished film from traditional arts such as painting, music, and literature by insisting that film is simultaneously an art and an industry. Cinema's industrialized processes differ from the artisanal, craft-based traditional arts in ways that separate the historiography of film from that of the other arts in three respects. First, films, as products of an industrial system, invite a variety of humanistic, psychological, and social scientific forms of analysis, ranging from traditional art-historical approaches centered on aesthetics and filmmakers' biographies to diverse economic, technological, sociopolitical, and quasianthropological investigations (Allen and Gomery, 1985; Lagny, 1992). Film history's object of study is rarely defined exclusively in aesthetic terms, as is evident in the long-standing practice of demarcating periods in film history by nonaesthetic events, such as the beginning of the First World War or the end of the Second World War. Even film histories concerned mainly with aesthetic questions typically also situate films in economic, technological, and social contexts; and certain film histories conceptualize film primarily as a technological, economic, and/or social phenomenon, to the point of excluding aesthetic considerations altogether, as in studies of the economics of national film industries.

Second, the industrial nature of much film production has encouraged modernist conceptions of historical change according to which film history moves forward, in a single direction, with new films counting as a technical if not aesthetic advance over old. This newer-is-better conception of change is promulgated by the entertainment industry itself, and it differs from the cyclical patterns of the histories of the established fine arts, where artistic movements are seen to rise, fall, and emerge again in the manner of the life cycle of a natural organism. Filmmaking, so evidently a function of technological, industrial, and commercial conditions and forces, invites conceptualization as an ongoing, forward-moving process, forever open to additional improvement. This conception of historical change as a modernizing process informs both the film industry's celebration of the latest advances in film technique and critics' nostalgia for the lost artistry of the filmmaking of earlier periods.

A third peculiarity of film as an object of historical research concerns the relatively short duration of cinema history, which has led film historians to reexamine the cinema's past in light of present-day developments (Bordwell, 1997). The focus on what the art form's present suggests of its past – and vice versa, what the art's past may reveal of its current possibilities – is unusual in the much longer histories of painting, poetry, and music, which typically are studied irrespective of present-day artistic developments (Belting, 1987). Film

historians, however, are concerned with an art whose past coincides with a recent and relatively short span of historical time, to the point that new understandings of film history have long been motivated by current developments in film practice. In the 1930s, for instance, the conversion to sound cinema had made it seem as if 'silent' films belonged to the historical past, thereby providing justification for the creation of film archives in Germany, Britain, the United States, France, and elsewhere. Something similar is happening in the early twenty-first century, as the introduction of digital film production and exhibition pushes historians to see the cinema's past in new ways. For instance, as computer-generated digital images supersede photochemical images, cartoons, and other nonphotographic animated films increasingly appear central rather than peripheral to film history. In any case, film-historical reasoning often displays a retrospective orientation in which the cinema's past comes up as a prelude to the cinema of the historian's present, which, for better or worse, provides a context for making sense of the historical past.

A Chronology under Revision

What follows below is a chronology of world cinema that discusses historiographical developments pertaining to specific periods. Keep in mind that the chronology in question concerns developments primarily in the United States and Europe, and may well require revision insofar as the focus of inquiry shifts toward cinema in other parts of the world, where analogous events happened, but often later.

Early Cinema, 1895–1906

Research on the so-called early cinema of 1895–1906 exemplifies contemporary film historiography's concern with films as embedded within contemporaneous contexts of production, exhibition, and reception. Early cinema is taken to begin in the mid-1890s with the first screenings of films by inventors of motion picture cameras and projectors, such as the Lumière brothers in France and the Skladonowsky brothers in Germany in late 1895, and, in early 1896, by Birt Acres in London and Thomas Edison in the United States. The period continues until roughly 1906, when narrative films began to dominate the film industry's output and the exhibition sites were no longer mainly fairgrounds, vaudeville houses, and rented theaters but nickelodeons and other permanent venues intended specifically for motion picture screenings.

Accounts of early cinema often center on the development of techniques of film editing, whose rapid evolution can be traced in films at the turn of the twentieth century. The films of inventors such as Edison and the Lumières were made up of only a single shot, usually lasting the length of a standard reel of film. But by 1899, in response to a greatly increased demand for motion pictures, film companies in France, England, and the United States began producing narrative films made up of multiple shots. Historians have analyzed these films as attempts to solve the problem of how separate shots might be staged and connected together to create the impression of continuous story action.

Film historians initially treated early multiple-shot films such as *The Great Train Robbery* (Edwin Porter, 1903) as landmarks in the development of the system of stylistic conventions associated with studio-era Hollywood (Jacobs, 1939). Since the late-1970s, however, a very different history of the cinema of 1895–1906 has been written (see Elsaesser and Barker, 1990). Instead of a forerunner of the commercial narrative cinema of the late 1910s, early films are examined in the context of their function relative to vaudeville routines, illustrated song slides, public lectures, and other forms of popular spectacle entertainment. Examining how musical performance, spoken narration, and other exhibition practices affected the viewing experience, recent studies of early cinema bring forth dimensions of early films occluded within traditional developmental accounts. An example is the theatrical or presentational aspect of early cinema, which became a focus of historical study in the 1980s. Investigating early cinema's practices of direct address, adapted from vaudeville, the fairground, the magic show, and other forms of popular theater, historians have come to understand early films less as primitive attempts at classical storytelling and more as performances within the context of live, spectacle entertainment at the turn of the century (Gaudreault, 2010). Innovations in early cinema research continue to inspire research into other periods of film and media history.

The Transition to Classicism

The cinema of the period 1906–17 has traditionally been conceptualized as a transition from early cinema to the feature films produced at the Hollywood studios of the late-teens. Key industrial developments include: a shift in editorial control away from exhibitors and toward producers; the creation of exchanges that rented film prints to exhibitors rather than sold them outright; the organization of film production according to a hierarchical division of labor that gave producers authority over directors and camera operators; the establishment of Hollywood as a production center; and the cinema's further expansion worldwide, marked, for instance, by the emergence of Denmark and Italy as major film-producing countries. Style-related developments of 1906–17 include: the dominance of the fiction film over the vaudeville-like attractions and documentary 'actualities' of early cinema; the emergence of celebrity performers or 'stars'; and a continuing increase in film length, leading, by 1914, to the establishment of the feature-length multireel film as the default format for commercial moviemaking.

Accounts of the transition to classicism often stress the development of devices of film editing (Salt, 2009). As early as the late-aughts, critics noted that editing enabled forms of acting unique to cinema, with actors' performances constructed through a planned assembly of numerous shots rather than captured in a lengthy, uninterrupted run of the camera. Editing allowed the filmmaker to direct the viewer's attention in a manner unimaginable in traditional theatrical entertainments, just as close placement of the actors relative to the camera allowed for a new, naturalistic acting technique. During the 1920s, filmmakers and theorists in France, the Soviet Union, and elsewhere argued that editing had differentiated film from theater to the point of establishing film as a singular art.

Accounts of the cinema of the 1910s have emphasized the work of director D.W. Griffith, who has been credited with having conceived of a motion picture less as a performance staged for the camera than as a composite of shots, staged, filmed, and assembled so as to construct a unified dramatic world. In some 480 short one- and two-reel films directed by Griffith between 1908 and 1913, devices such as the close-up, crosscutting, and the eyeline match are employed as elements within what film theorists have described as a storytelling 'language' unique to cinema. In films such as *The Girl and Her Trust* (Griffith, 1912), a one-reel film made up of nearly 130 shots, elaborate last-minute rescues include events occurring in three separate locales, cut together in rhythms that accelerate or slowdown relative to the intensity of the dramatic action. Since 1990, historians have challenged the idea that Griffith's editing provided the basis for the classical style that would take form in Hollywood circa 1917 by proposing instead that Griffith was a transitional figure whose style was peculiar to him in important respects (Gunning, 1991).

Also in the 1990s, the rediscovery of early films from Russia and Germany led historians to question the traditional emphasis in film historiography on editing practices and argue that a proper appreciation of cinema requires careful attention to mise-en-scène as well, to the staging of the dramatic action through the arrangement of actors, settings, and props within the camera's visual field (Brewster and Jacobs, 1997). Such attention is especially warranted for films made outside the United States, whose stories, in crucial respects, were told through techniques of staging rather than cutting. The film industries of Italy, Russia, France, Denmark, Sweden, and Germany, for instance, produced hundreds of narrative films with scenes playing out in extended long takes. Using far fewer shots than American films, European films of the 1910s often delineate story events through the careful choreography of multiple actors' movements within the film's frame. Ensemble performances in which the dramatic action involves several actors within a common framing situate character interactions within a shared environment; European films of the 1910s might thus be said to exhibit a social dimension less available to the contemporaneous American cinema's stress on linear, physical action.

National Cinemas

By 1918, with the disruption of Europe's film industries by the First World War, Hollywood had established itself as the world's foremost film exporter, with distribution branches in South America, Australia, the Far East, and Europe (Thompson and Bordwell, 2010). In response to Hollywood's new preeminence, Europe's film industries imposed quotas and other trade restrictions on Hollywood films, and drew inspiration from modernist trends in the arts to invent distinctive national film styles. From Expressionism and the Neue Sachlichkeit ('New Objectivity') in Germany to impressionism and surrealism in France and constructivism in the Soviet Union, the major national art cinemas of the 1920s inspired much reflection on film as an art, manifest, for one, in a large and sophisticated body of film-theoretical writing. In France, where there was no clear industrial division between commercial cinema and art cinema, avant-garde techniques were integral to many mainstream films.

The experimental film movements evolved within a new international film culture, organized around specialized journals, film clubs, and art-cinema theaters. An unprecedented intellectual interest in film stimulated theoretical writings and manifestos stressing the need to overcome the apparent theatricality of established film styles; and numerous filmmakers in Europe and elsewhere undertook radical explorations of film's artistic potential. As a consequence, the major European art films of the 1920s frequently exhibit many more shots than had earlier European films, along with an array of experimental cinematographic devices, from filtered lenses to superimposed images, double-exposures, and split-screen compositions.

Certain national film movements of the 1920s became known for exploring film's potential for radical alternatives to conventional scenography. Prominent examples include: the montage films of the Soviet Union, such as *The Battleship Potemkin* (Sergei Eisenstein, 1925) and *Man with a Movie Camera* (Dziga Vertov, 1929), famous for their aggressive experimentation in film editing; and French Impressionist films, from the pathbreaking *Fièvre* (Louis Delluc, 1921) to diverse films by directors such as Germaine Dulac, Jean Epstein, and Abel Gance, who employed multiple superimpositions and other optical effects to simulate the flux of diverse moods, feelings, and emotions. German films such as *The Cabinet of Dr. Caligari* (Robert Weine, 1920) and *Metropolis* (Fritz Lang, 1927) won international acclaim for their spectacular, studio-created settings, while *The Last Laugh* (F.W. Murnau, 1924) was celebrated for optical effects and elaborate moving camera shots that suggest a character's psychological 'point of view.' By the mid-1920s, with increasing numbers of films, artists, and critics crossing national borders, an international avant-garde had taken form, encompassing filmmakers in Europe, North America, and Japan, and exemplified by 'international' films, such as *Page of Madness* (Teinosuke Kinugasa, 1926) and *La Passion de Jeanne d'Arc* (Carl Dreyer, 1928), which confounded national labels with their unusual mix of styles (Thompson and Bordwell, 2010).

Questions remain open concerning how new research might alter the historiography of world cinema in the 1920s. One topic concerns the popular cinemas of the major Western countries, which has long been neglected in favor of the export-oriented art films. A further topic concerns cinema outside the United States, France, and Germany. In the 1920s, for instance, Japan and India were among the world's largest film-producing countries; yet, as with many other national cinemas during the years between the World Wars, the films were rarely distributed beyond the national and regional film markets, and extremely few have been preserved by distributors and archives. Although Japan's large film industry dates from the 1920s, research on the history of Japanese cinema began to flourish only in the 1970s, with the rediscovery of the pre-World War II films of Yasujiro Ozu, Kenji Mizoguchi, and other prominent art-cinema directors. Assessments of world cinema during the 1920s are certain to undergo revision, pending further research into the variety of film industries of the period, and their sometimes asynchronous chronologies. Pending the availability of studies of popular cinemas from around the world,

historical assessments of world cinema in the 1920s remain incomplete and provisional.

The Conversion to Sound Cinema

The introduction of recorded sound to cinema has attracted much analysis and commentary, which began as early as the late 1920s with the international success of films such as *The Singing Fool* (Lloyd Bacon, 1928), which provoked debate worldwide concerning the future of cinema. In the summer of 1928, as the film industry in the United States began its conversion to sound, observers described synchronous sound as nothing less than an artistic, technological, and economic revolution. The sense of crisis went on to inform subsequent historical accounts of the conversion period, which have traditionally emphasized traumatic changes such as: the sudden collapse of the careers of established actors and other talent; the flood of new stage, musical, and technical personnel into the film industry; the technical and aesthetic limitations of early sound films; the refinancing of the film industry by large banks; and the curtailment of avant-garde experimentation brought about by the high costs of sound-film production. The condition of crisis encouraged partisan assessments, whether in the form of Hollywood's celebration of sound cinema as a great democratic advance or critics' nostalgia for the vanished art of silent film. In either case, film history had seemed to start over again with the introduction of recorded sound.

Concerning film aesthetics, sound conversion is said to have produced two main consequences. First, the first sound films sometimes displayed relatively long takes, stationary framings, and immobile actors who recited dialogue in styles familiar to the popular stage, and thus counted for numerous critics as an artistic regression from the ambitious art films of the mid-1920s. Challenging the idea that sound cinema amounted to an artistic catastrophe, established histories of the early sound years have focused on exceptional films such as *Applause* (Rouben Mamoulian, 1929), *Sous les toits de Paris* (René Clair, 1930), and *M* (Fritz Lang, 1931), whose innovations in multitrack recording, postsynchronization, playback, and other techniques are credited with having restored movement to the movies. More recently, historians have expanded their purview to encompass vast numbers of ordinary films of the time (Crafton, 1997).

Second, the technical demands of sound-filmmaking appeared to push filmmakers everywhere toward adoption of important aspects of Hollywood's approach to style and narration. For critics familiar with the distinctive national film styles and transnational film movements of the 1920s, sound films often seemed to belong to a common family, regardless of where they were made. Even the Soviet Union, famous during the 1920s for its counter-Hollywood film culture, was, by 1934, producing films that looked and sounded much like commercial narrative films made elsewhere. By the late 1930s, filmmakers, in countries throughout the world, including Japan and China, were making sound movies in imitation of Hollywood's approach to storytelling.

In assessing sound's impact on film style, it is important to distinguish between filmmaking in Hollywood, which had already undergone full industrialization prior to sound conversion, and filmmaking in other countries, which was still largely artisanal when sound was introduced. Whatever the personal, technical, and administrative upheaval, Hollywood's processes of serial manufacture remained largely unchanged, which enabled a continuation of important aspects of silent-era film technique. Most notably, Hollywood's sound-era editing style remained essentially consistent with established methods for constructing a unified, linear narrative (Bazin, 1967). After a brief period of experimentation, the new sound techniques were brought into line with artistic precedent (Lastra, 2000). For instance, in 'backstage musicals' such as *The Broadway Melody* (Harry Beaumont, 1929), song-and-dance sequences came forward less as recordings of self-contained performances than contributions to narratives about the offstage lives of show-business personalities. By the summer of 1931, with the industry-wide adoption of multitrack recording and mixing, the foregrounding of sound technique as an artistic novelty had been abandoned in favor of the emphasis on storytelling characteristic of Hollywood films of the late-silent period.

In many countries, however, sound conversion had entailed fundamental industrial change, and hence consequences for film aesthetics that were more radical than in Hollywood. In India and Mexico, for instance, where filmmaking had been minimally industrialized, complete restructuring of the industry occurred, and new, sound-era genres, such as musicals that drew upon indigenous and regional entertainment traditions, came to define the national film output. Research into the worldwide conversion to sound remains in its early stages. As with cinema during the preceding decade, relatively little is known about the output of many national film industries of the 1930s.

Postwar Internationalism

The decade after the Second World War is known for the emergence of a revived international art cinema. Prominent institutional developments include: the creation of international film festivals in cities such as Cannes, Venice, Berlin, Edinburgh, and Tokyo; increased government funding of film archives, thereby enabling expansion worldwide of the International Federation of Film Archives; new film journals devoted to international coverage; and the opening of special art-house movie theaters in cities throughout the world. These developments had prewar antecedents that led observers to note parallels between the new art cinema and the international avant-garde of the 1920s. Where the new film culture differed was in the extent to which its global network of festivals functioned independently from nation-state institutions. An example can be found in the worldwide reception of Italian neorealism, whose status as the preeminent postwar film movement depended crucially on critical acclaim from outside Italy. More popular abroad than at home, films such as *Rome, Open City* (Roberto Rossellini, 1945), and *Bicycle Thieves* (Vittorio De Sica, 1948) drew admiration from filmmakers from every continent. Essential here were innovations in narrative. In contrast to the commercial cinema's linear and formulaic, genre-based plots, the neorealist films emphasized the acts and events of ordinary life, including chance occurrences, routine, nondramatic actions, and inconclusive chains of events. Neorealist films were also acclaimed for the documentary-like 'realism' manifest in their use of nonprofessional

actors, improvised performances, actual locations, and natural lighting.

Neorealism is said to have affected filmmaking in Asia, Africa, and Latin America more so than any other film movement of the sound era, and it has commanded attention from historians as a beginning for prominent subsequent movements and tendencies in world cinema. Neorealism offered a coherent, low-budget alternative to commercial cinema, with great potential both for naturalistic social representation and for sociopolitical allegory. Filmmakers who have cited Italian neorealism as a personal inspiration include: Fernando Birra and Tomás Gutiérrez Alea, leading directors during the 1960s in the film industries of Argentina and Cuba, respectively; Satyajit Ray, the famous Bengali director from the Indian subcontinent; Bollywood pioneer Raj Kapoor; and Nelson Pereira dos Santos, founder of the Cinema Novo movement in Brazil.

The emergence of innovative film movements in Latin America, Asia, and, by the late 1960s, in Africa, with the rise to prominence of the Senegalese director Ousmane Sembene, had been conditioned by two basic developments. First, in 1947, movie attendance in North America had begun to fall, and would continue to do so for the next two decades. The decline became apparent just as Hollywood faced the landmark 1948 decision by the U.S. Supreme Court that required that the five major studios sell off their theater chains, and that both major and minor studios cease a variety of monopolistic practices. In response to the economic and political adversity, the major Hollywood studios produced fewer films in the 1950s, and they began targeting smaller, more specific markets. Second, during this same period, in many countries around the world, booms in film attendance occurred. Attendance increases were especially pronounced in the so-called developing world, where television had not yet emerged as an entertainment alternative. Responding to the new demand for motion pictures, major film industries emerged in Egypt and Hong Kong, while the new nations of Burma, Pakistan, South Korea, and the Philippines also began producing films on an industrial scale. In the 1950s, India became one of the world's largest film producers, making hundreds of films exclusively for the South Asian film market. By the mid-1960s, some 60% of all of the world's feature films came from Asia, Latin America, and Africa (Thompson and Bordwell, 2010).

Coinciding with the worldwide boom in film production, young filmmakers worked to distinguish themselves from the previous generation by emulating new currents in world cinema. 'New waves' and 'young cinemas' took form in diverse countries, beginning in the late 1950s and continuing through the 1960s. Most prominent was the French New Wave, known for films such as *Les quatre cent coups* (François Truffaut, 1959), *Breathless* (Jean-Luc Godard, 1960), and *Hiroshima mon amour* (Alain Resnais, 1959), which featured inventive adaptations of conventions drawn from Hollywood and European genre films and also from the international art cinema. Further important new wave movements emerged in the 1960s in Japan, Czechoslovakia, Portugal, and, indeed, in virtually all countries, in one form or another. A famous example is the Young German Cinema, whose self-conscious opposition to Germany's established film culture opened the way for the international prominence in the 1970s of directors such as R.W. Fassbinder, Werner Herzog, and Wim Wenders.

Film Historiography since the 1970s

The new film culture of the 1960s had a profound impact on the writing of film history. An example can be found in the notion of the film director as artist or 'auteur.' Formulated in Paris in the 1950s by a group of young film critics, some of whom went to become key directors of the French New Wave, the notion of the auteur attributed to certain film directors the kind of creative role traditionally accorded to novelists, playwrights, painters, and composers. A precedent for the filmmaker-as-artist concept can be found in certain currents in film critical writing in the 1920s, which had celebrated the artistry of D.W. Griffith, Charlie Chaplin, F.W. Murnau, Erich von Stroheim, and others. But the auteur critics extended the sphere of art to encompass a remarkable diversity of films, including, in some cases, low-budget sound-era genre pictures. Provocatively comparing commercial movie directors to Mozart and Shakespeare, the auteur critics expanded the canon of great film artists to include current commercial directors such as John Ford, Orson Welles, Alfred Hitchcock, and Howard Hawks.

The 1970s marked the integration of film study into university curricula in Western countries, which opened a new, professionalized era in film historiography marked by an ongoing critical reexamination of established film history. A case in point is the new historiography of silent cinema. While previous film historians had often relied on other historians' accounts, together with personal memories of films, the new generation of archivists and professional scholars studied large collections of film prints, comprised of recognized classics as well as many lesser known or forgotten works. These historians also examined a wide variety of print documents, from film reviews to trade publications, film company catalogs, and paper prints of films from the U.S. Library of Congress. Silent-film festivals, conferences, and journal publications facilitated debate and discussion among historians. The result of these developments was a thorough reconceptualization of the early silent period, which, in turn, has served to inspire historians working on later periods.

As cinema now enters its second century as a thriving art and entertainment, new technological changes provoke new ways of seeing the cinema's past. At annual festivals, such as those held in Bologna and Pordenone, large bodies of films, representing the output of diverse directors, actors, studios, film movements, and national cinemas, are made accessible to critics and historians. Some of this material has found it way to DVD and other formats for digital distribution, which has vastly increased the availability of these films to researchers. With so much research material now available online, the nature of film-historical research is changing (Loiperdinger, 2003). Films virtually impossible to see a few decades ago are now readily available in beautiful restored copies. As old films continue to be restored and made available to scholars, significant changes in film historiography continue to occur. Online archives, chat groups, and blogs are making possible further interchange between scholars as well as new sorts of research projects – as are computer-based tools such as the cinemetrics interface, which allows the critic to perform easily

various statistical measurements of film editing (Tsivian, 2009). Each year, new discoveries stimulate revision of established scholarship just as they underline the incompleteness of the historical record, and hence the certainty that the study of film history will remain a work-in-progress.

Abstract

The anthropology of finance is composed of an interdisciplinary set of approaches for analyzing the mechanisms, worldviews, networks, and far-reaching socioeconomic effects of finance. Given the influence of financial values and practices, not to mention the tendency for academic and public approaches to finance to further obscure its workings, anthropology's ethnographic toolkit has a crucial role to play in unpacking the cultural specificities and underpinnings of finance. Indebted to and in conversation with many subfields, from economic sociology to political economy, the anthropology of finance navigates the theoretical and methodological challenges of abstraction and old binaries of economy and society to investigate the contours and consequences of finance and financialization.

Introduction

The anthropology of finance has engaged broadly with the social dynamic of financialization, as well as the importance and centrality of financial markets, institutions, values, and practices in the global social economy and everyday life. Given the pervasive influence of finance in our world, coupled with the production of highly specialized knowledge among financial actors and networks, the anthropology of finance has made important contributions toward a deeper understanding of the products, practices, ideologies, and socioeconomic consequences of finance and financialization. In particular, anthropology has brought to the study of finance its fine-grained ethnographic methods of participant observation, long-term immersion, and polymorphous engagements with natives' points of view, practices, and everyday lives.

These anthropological approaches are especially useful given that finance as an ethnographic site is not only characterized by inaccessibility to outsiders, specialized knowledge, and continual change and innovation, but is also framed by the larger culture as both mystifying and acultural. While certainly all sites of ethnographic investigation should be understood as possessing nuance and complexity, finance has perpetuated its rarified air through both 'inside' and 'outside' representations of its opacity. Anthropology thus bears a greater responsibility to use its toolkit to unpack the mechanisms, relations, and effects of finance and financialization in a way that resists conflation with broader cultural assumptions.

By finance, I refer to a constellation of priorities, practices, and ideologies that, in the context of a market economy, are mobilized to search for and convert already existing assets (including both tangible possessions, such as corporations and real estate, and personal attributes and status markers, such as educational background and credentials) into income streams, investments, or immediate profits. In order to 'realize' these assets as liquid monetary forms, intersecting cultural, material, political, and legal transformations need to occur such that these often nonfinancial assets are emplaced into commoditized spaces of exchange that allow for the conversion of these assets. For example, when relocated and reimagined as financial assets within spaces of exchange, sites such as large corporations, which were previously understood to be long-term social institutions, are 'converted' into their stock prices and thus become easier to buy, sell, and/or disassemble. Similarly, in this commoditized space, assets such as homes and mortgages are bundled, repackaged, and converted into 'collateralized debt obligations,' which are financial instruments sold as high-yield investments using the homes themselves as collateral and mortgage holders' payments as income streams. A social economy characterized by financial dominance thus actively searches for and converts assets into prices or securitized debt so that they can be bought and sold, and it is through these acts of exchange that financial institutions, actors, and interests amass influence and generate income.

It is important to emphasize that 'financialization' refers to the growing influence of finance, specifically the translations and interactions between financial modes of apprehending the world and other social domains. Institutions, natural resources, governmental entities, education, retirements, and so on are all increasingly dependent on financial products, measurements, and values. The processes of financialization, moreover, are uneven, specific, and contingent, creating major structural changes in the social landscape. This 'scaling up' does not only refer to the far-reaching influence of finance institutionally, regionally, and globally, but also to its remaking of 'individual' subjectivities and selves. Financialization, as Randy Martin (2002) shows in *Financialization of Everyday Life*, is concomitantly about the restructuring of the self through the alteration of intimate beliefs and practices. While the expanding sphere of finance might seem recent as well as deeply intentional, it is crucial to recognize that greater financialization is also a story of unintended consequences. For different but also intersecting reasons, policymakers, business advocates, and reformers alike turned to finance over the course of the twentieth century as an alternative site 'outside' of the state and its sedimented exclusions to attempt to both solve credit discrimination and fund increasing middle-class consumption, as well as obscure (and temper) growing sociopolitical unrest, declining wages, and struggles for inclusion (Hyman, 2012; Krippner, 2012; Ott, 2011; van der Zwan, 2013). That finance heightened socioeconomic inequalities and produced new kinds of desires, dependences, and precarity without solving poverty and disenfranchisement is precisely one of the central problems of the twenty-first century.

Specifically, in the US corporate context, financialization has meant that the growth of financial activities has become a key source of profits for financial and nonfinancial corporations alike. By the 1980s, American financial institutions had shifted away from funding the production of goods and services toward activities and financial transactions such as consumer lending, mergers and acquisitions, and trading securities and derivatives. Meanwhile, nonfinancial corporations increasingly shied away from long-term fixed investments in plant, equipment, and research and development. Instead, they too diverted capital to finance. The result was a redistribution of wealth toward certain investors and financial advisors, an explosion in the compensation of financiers and in stock-related incentives for corporate CEOs, increasing socioeconomic inequality, and a far more volatile economy periodically besieged by restructuring and financial crisis – all validated by the discourse of shareholder maximization and an increasingly predatory and short-term banking culture.

While anthropology has made important strides in studying both finance (especially from sites of expertise) and financialization (especially from 'below'), we have not been as effective in analyzing the concrete linkages between them, between the *mechanisms* of finance and the *effects* of financialization. Moreover, given that we have historically studied both capitalism and financialization from the vantage point of the less powerful, *and* given that recent ethnographic studies of finance have focused on financial products, networks, structures, knowledges, and ethics *without* necessarily examining how they *financialize*, anthropology may be running the risk of reproducing the point of view and epistemology of its more powerful subjects, as well as their idea as to what constitutes the proper subjects and objects of finance.

Central Assumptions and Challenges

To better understand and assess the challenges faced by the anthropology of finance and financialization and the potential directions it might take, an examination of our contemporary socioeconomic landscape as well as the dominant academic assumptions and analyses of these transformations would now be instructive. In the larger public imaginary, not to mention in the assumptions of critical scholars, finance is often simultaneously and negatively framed as separate from or antithetical to the 'real' economy, to production and productivity, while in the same breath it is automatically associated with inequality, 'fat cats,' and speculation. As such, many social analysts and critics, especially in the wake of the financial practices that helped to engender the Great Recession of 2008, have followed dominant interpretative paths for apprehending and critiquing finance, which are certainly understandable, yet also potentially misleading.

For example, mainstream assumptions associate finance with abstraction (i.e., distance and disconnection from 'the real' economy) and inequality, theorizing that the former produces the latter. Multiple assumptions are at work here that are crucial to unpack. First, the simplistic association of finance with abstraction discourages analysis of the workings and cultural processes of finance in that it further naturalizes the notion that finance is removed from everyday life and difficult to understand. Such an approach not only lets finance off the hook, it also falls prey to the rule of expertise whereupon the architects of unsustainable financial leverage are precisely those charged with diagnosing, explaining, and fixing its failures – because they are 'the smartest guys in the room.' Furthermore, abstraction also conveys and perpetuates the notion that financial crisis is the regrettable but unavoidable byproduct of the complexity of finance itself (La Berge, 2014). These rhetorics and tropes, again, cede authority to the experts themselves.

Abstraction and its twin complexity are also implicated as the central causes of the growing inequality in our social economy. In other words, the taken-for-granted understanding is that finance leads to inequality because its actions, focused as they are on short-term profiteering and making money out of money, have been divorced from 'real' production, the 'true' engine of creating jobs and manufacturing wealth. It was this sentiment, coupled with widespread public discontent, that fueled the ubiquitous and effective 'vulture capitalism' critiques of 2012 Republican presidential nominee Mitt Romney, in which he was accused of stripping and dismembering corporations and jobs for financial profit. Such an explanatory narrative of increasing abstraction as causing inequality is certainly understandable given the ever-widening wealth gap, and the inaccessibility and seeming remoteness of finance in the public imagination. Yet, if the culprit of growing inequality is abstraction itself – not the actions, practices, structures, and ideologies of financial actors and institutions – then it is not surprising that nebulousness characterizes our thinking about, critiques of, and general approach to finance.

Critical Approaches to Finance

This thread of addressing abstraction is an instructive one to think through in relation to anthropological and broader social scientific accounts of finance. While critical approaches to finance have overall been quite diverse and multidisciplinary, to the extent that certain orthodoxies have been reproduced in this scholarship, they cohere around the redichotomizing of the domains of economy and society as well as around perpetuating the taken-for-granted 'characteristics' of finance as abstract and corrosive in contradistinction to more 'authentic' and moral forms of economy and social relations. Because the practices, relationships, and values that are presumed to belong to the constructed domains of 'economy' and 'society,' not to mention the very manner in which these categories are thought to relate to each other, are so deeply engrained in US and western cosmologies (and presumed to be self-evident), critical scholarship is not exempt from these normative assumptions.

As such, it is not surprising that at one time or another, much of existing social scientific scholarship on finance reproduces a certain economism, or formalistic understanding of money and finance. For example, groundbreaking subfields such as economic sociology – which have contributed immensely to broader social scientific debates and understandings about the social construction of markets, the role of institutions and social networks, as well as the meanings and moralities of market forms and products – can, at times, fall prey to the reproduction of artificial binaries between economy

and society through its use of the narrative of the market 'disembedding from society.' The problem with this embeddedness paradigm is that demonstrating that 'the market' is, in fact, 'embedded' in society inadvertently perpetuates the assumption that 'market' and 'society' are stable categories and separable domains in the first place. While this re-embedding argument made sense as an intervention against the narrow mythologies of neoclassical economics, it is not a "great organizing principle for economy sociology" (Krippner and Alvarez, 2007).

Similarly, approaches from cultural economy to political economy, while demonstrating the mutual constitution of 'economy' and 'culture,' not to mention the structures of power that imbue capitalist social relations, can also reproduce economy/society binaries by framing 'finance' as a corrosive force against society. In this framing, finance is not only external to society, but also positioned as the immoral antithesis of a moral society; the solution is thus to re-embed and regulate finance. At issue is not the fact that the dominance of finance is leading to increased inequality (that is certainly the case); rather, it is that in highlighting the effects of inequality, we are assuming preformed 'market logics' for culturally specific and historically contingent financial values, priorities, and practices. In other words, the linear narrative of finance as a distant, autonomous, 'bottom line' economic force that colonizes society and catalyzes inequality sets the stage for the assumptions of corrosiveness and immorality. And, while the notion that finance is morally suspect and destructive is certainly an important contemporary sentiment, the analytical consequences of this frustration are that we absolve ourselves from investigating the mechanisms, categories, and assumptions of finance that are culturally and institutionally conditioned. Representing finance as disconnected and depraved depends on and reproduces a problematic narrative of authentic and inauthentic modes of capitalism, where finance is considered less authentic because it subverts normative productive capitalism due to its ability to self-reproduce from a distance without real productive labor or *longue durée* investments.

Yet another compelling approach to apprehending finance is what might be dubbed the social studies of finance, which itself derives loosely from interdisciplinary scholarship in science and technology studies and actor-network theories. This conceptual and theoretical trajectory has focused on the technology, networks, and architectures of markets – systems, models, objects, products, knowledges, and their relationships with each other and with the larger world. Such an approach has been crucial to the cultural study of markets and finance precisely because of its fine-grained analysis and tracking of the operations, formulas, and procedures that produce and structure finance (Knorr Cetina, 2007; Knorr Cetina and Preda, 2004; Lépinay, 2011). Its major contributions have included the training of attention on the interactions and interfaces between human and nonhuman actors that make financial transactions and knowledge production possible, as well as a focus on the interior architecture of finance almost akin to 'laboratory studies' that has helped to unravel the mechanics of the making of financial expertise. Its attention to the 'interiorities' of financial markets explores specifically how financial formulas and codes, interactions with prices, screens, and fellow analysts, and embodied understandings of numbers, volatilities, time, and space all participate in the construction of market architecture and the flows that permeate it. However, this literature's occasional framing of finance as a second-order market that is separate from actual firms and industrial production, or 'primary producer markets,' reproduces the very binaries that have been challenged earlier. Finance, it is important to emphasize, is intimately linked to production; it *does* depend on taking advantage of production, on converting a variety of assets into financial profits. Since finance is not so much separate from production as it is dependent on (and exploitative of) it, presuming disconnection or abstraction misses the point. Focusing too much on the interior workings of finance can make it difficult to simultaneously pay attention to the consequences of financialization, especially the production of socioeconomic inequality.

Perhaps the most influential contribution from this approach has been what is often termed 'performativity,' specifically the examination of how and to what extent formal economic models – the technologies and market devices described earlier – structure financial markets through the process of enacting and attempting to 'realize' these models (Fligstein and Dauter, 2007). This body of work has demonstrated how the implementation of reductive economic models and ideas (and the setting of these theories as goals to strive toward) has helped to construct socioeconomic realities that are framed by and akin to these representations (Callon, 1998; Callon et al., 2007; Carrier and Miller, 1998). Such work is crucial because it portrays the field of economics as a discipline involved in the active production of our world, not simply modeling it. Parallel to and building on the performativity of economics approach, sociologists of markets have not only demonstrated how mathematical and financial models help to 'make' markets (i.e., help to actualize some of what they model), but also shown that these models are mediated, influenced, and interpreted through organizational and institutional cultures that are also crucial to market-making (Beunza and David, 2008, 2012; Mackenzie, 2006; Mackenzie et al., 2008). Interestingly, this literature, while impactful in a multiplicity of ways, has also recently been critiqued for reproducing economic essentialism and a kind of inadvertent economism. Given its demonstration of the power of formal economic models, this subfield also runs the risk of including only certain sets of practices under the rubric of 'the economic' and overprivileging the capacity of certain market devices to remake the world.

In general, anthropological engagements with finance draw from and build on the many contributions of the aforementioned subfields. Given that finance continues to exercise an outsized influence over our social economy – its practices and sensibilities are utilized to govern and discipline a multitude of social domains and resources – a variety of cross-cutting and interdisciplinary research on finance is crucial. Paralleling these subfields, the anthropology of finance, forged by the larger discipline's history of engaging with capitalism and money, sheds light on 'the financial turn' by innovatively using anthropology's 'hallmark' methods of participant observation, of training and adoption, while it also reproduces some of our recurring analytical pitfalls

regarding the abstraction and economism of market logics (Maurer, 2012).

As the anthropologist Bill Maurer has concluded, using 'the broadest definition of finance,' the anthropology of finance 'would include all aspects of the management of money,' and in this general sense, finance has long been a core part of the anthropological tradition. The anthropologies of economy, capitalism, and colonialism, for example, have tackled the cultural construction of wealth and desires; shed light on multiple, alternative, and competing systems and values of exchange and reciprocity; interrogated the moral values, concepts, and cosmologies of western capitalism through the examination of exploitation at the margins; and demonstrated that imposed colonial systems of currency, credit, and debt, though influential and hierarchical, "were rarely more stable than those they sought to replace, and local systems were often durable and capable of sustaining long-distance and long-term financial relationships" (Maurer, 2012: p. 186).

In the anthropology of finance, then, the central tensions of challenging western universality through the figure and perspective of the other while simultaneously either eliding or homogenizing western capitalism are at work. For example, interrogating western assumptions of rationality and efficiency has been a central contribution of economic anthropology. Chris Hann and Keith Hart (2011) explain that in challenging the taken-for-grantedness of western economic categories and domains, economic anthropology importantly delved into alternative, culturally 'different,' and substantive ways of organizing and understanding affluence, household, reciprocity, and exchange. And yet, in their excavation of other ways of knowing, they also "removed world history from…[their] repertoire" (Hart, 2013: p. 1; Hann and Hart, 2011). In other words, in their attempts to focus on 'the other' and 'the alternative,' globalization, colonialism, and western capitalism were inadvertently bracketed off.

In a related development, some of the most trenchant critiques of western capitalism have come from anthropologists studying those living on the peripheries of global capitalism, where researchers have parlayed the cultural idioms and insights of 'the other' – as critical thinkers in their own right – to speak back to western capitalist culture (see, for example, Taussig, 1980; an exemplar of such work). Of course, such an approach was undoubtedly catalyzed by and intended to address the removal of world historical events from the purview of economic anthropology. And yet, a similar pitfall could be found here: although western capitalism was named and critiqued, it was not ethnographically explored nor rendered specific. These ensuing critiques held western capitalism itself to be a stable, homogenous, global penetrating logic that attempted to reframe the world in its image; 'the rest' of the world is thus charged with resisting the totalizing onslaught through 'local' cultural forms, values, and traditions.

Similarly, the anthropological scholarship on capitalism and neoliberalism has participated in the (re)production of universalizing discourses (such as the narrative of increasing abstraction), while it has also recognized and critiqued its own role in rendering neoliberalism overly totalizing, homogenizing, or top–down (see Ferguson, 2010; Gibson-Graham, 1996; Shever, 2012 for important interventions). Especially from the standpoints of the marginalized, critical studies of capitalism have been incisive and groundbreaking in their attention to both 'big picture' market developments and structures, and concrete strategies of negotiation in the face of growing inequality (Comaroff and Comaroff, 2000) and yet, in evoking this new world order, finance and financialization often get reified or homogenously evoked. Of course, given that the fine-grained study of financial worlds demands attention to the details of financial practice, ethnographic and cultural studies of finance and financial markets across multiple disciplines also serve as a crucial intervention against their taken-for-grantedness or presumed totalization.

Ethnographic Examples

Four relatively recent anthropological monographs of finance illustrate some of the insights, interventions, and perspectives that long-term ethnographic research on finance can offer. A brief tour of Caitlin Zaloom's *Out of the Pits: Traders and Technology from Chicago to London*, Hirokazu Miyazaki's *Arbitraging Japan: Dreams of Capitalism at the End of Finance*, Karen Ho's *Liquidated: An Ethnography of Wall Street*, and Alexandra Ourousoff's *Wall Street at War: The Secret Struggle for the Global Economy* will serve to demonstrate the range of current ethnographic work and the particular insights that can derive from such labors.

Caitlin Zaloom (2006) accesses traders' culturally and historically specific embodiments and approaches to financial futures markets as trading moved from the open-outcry pits to the screen, from Chicago to London, and from divergent understandings of who and what constituted the proper economic subject to represent and engage in the new global financial markets. In particular, she finds that an ethnographic approach that includes traders' cultivation of a 'feel' for the rhythms of the market, along with their techniques of speculation and understandings of networks and competitors, affords more crucial insights into their daily market practices than simply an interrogation of their knowledge of the financial products themselves. In fact, it is through Zaloom's fine-grained research among traders that she then recognizes why dominant critiques of 'greed' and 'client responsibility' are oftentimes dismissed or ignored by these market actors. Given that the traders conceive their own central virtue or 'ethics' to derive from their ability to 'be' and to 'make' markets through aggressively facilitating and exploiting buyers and sellers, it comes to no surprise that they would register the act of habitually taking positions opposed to the interests of their own clients as part of their market-making responsibility, not simply being 'greedy' (Zaloom, 2012). To the extent that the anthropology of finance can better illuminate the motivations and specificities of such value registers, perhaps additional and more effective interventions can be made.

Hirokazu Miyazaki's ethnography (2013) delves into the ethics, knowledge practices, and dreams of Japanese traders in Tokyo as a window into the deep interiorities of the mindset and dreams of professional market actors. One of the ethnography's key contributions and methodologies is

that instead of framing the anthropologist as analyzing subject and approaching these actors as objects of critique, Miyazaki's work approaches and represents derivative traders as "thinking subjects capable of reflecting on and reorienting the place of their expertise in economy and society" (p. 23). In other words, financial professionals learn, observe, and theorize their worlds, techniques, and subjectivities in such a way as to recognize their limitations, failures, hopes, and dislocations. As such, especially in the context of the ruptures and uneven fortunes of some in finance (such as the Japanese arbitrageurs that Miyazaki studies in contradistinction to more privileged New York traders), it is crucial not only to understand how their 'ends' and 'means' have radically shifted, but also to grasp why calls to 'reform' and regulate finance need to take into consideration the multiplicity of experiences and goals that populate diverse financial worlds.

In Karen Ho's *Liquidated: An Ethnography of Wall Street* (2009), she accesses and examines the cosmologies of Wall Street investment bankers. The purpose of the study is to access their worldviews and analyze the processes through which such views are forged, as well as to understand how Wall Street values came to be imposed onto and emulated by other industries, thus setting the stage for the financialization of corporate America at large. According to Ho, the ethical outlook and professional practices of investment bankers are often obscured or rendered invisible by taken-for-granted 'marketspeak.' In other words, although 'financial culture' is constructed through institutional contexts, university pedigrees, and relationships with other financial institutions and corporate America, it is often mistaken for 'the market' itself, a presumption which in turn automatically rehearses neoclassical assumptions rather than revealing the cultural contingencies that underpin Wall Street. As such, one of the key contributions of *Liquidated* is to demonstrate that 'the market,' and other economic models and logics such as 'shareholder value,' cannot be taken at face value: the set of actions that is commonly held to result in rising stock prices is not predetermined by 'objective,' top–down formulas, but is instead constructed through the particular viewpoints and experiences of Wall Street bankers.

For example, it is precisely investment bankers' own experiences of continual restructuring, downsizing, and turnover, their short-term incentivization through year-end bonuses, and their understanding of front-office, 'revenue-generating' work as the only valuable labor (vs 'costly' back-office work that can easily be outsourced) that shape their ideas of how to create shareholder value. As a demonstration of the phenomena of financialization, *Liquidated* shows how Wall Street's local cultural models of business advice and practices have become so influential over the past 30 years. Other industries and sectors have had to take Wall Street's particularities so seriously that they have now become normative. The cultivation of a hierarchical superiority buttressed by a discourse of smartness, the revival of a particular ideology of shareholder primacy, the corporate takeover movement, and the massive transfer of wealth and assets into financial markets elevated Wall Street's role and influence. It was in this context that Wall Street financial institutions leveraged the supposed ability of bankers to act as market avatars to trigger the financialization of corporate America. Such ethnographic work unpacks and problematizes finance and financial markets by laying bare their cultural and historically contingent building blocks.

In *Wall Street at War*, Alexandra Ouroussoff (2010) further bridges the gap between finance and industry, between Wall Street and corporate America, in an ethnography that focuses on the tensions between the two models of economy and entrepreneurship. Through fieldwork with executives in the corporate and industrial sector on the one hand, and with financial analysts in the investment and financial sector, especially credit rating agencies, on the other, Ourousoff documents how the two models for conducting business have become paradoxically linked. In her analysis, the movement to discipline and measure corporate America according to the rules and norms of finance has helped to undermine the contemporary economy. Specifically, Ourousoff demonstrates that when Wall Street financial institutions and credit ratings agencies strive for investment predictability, the norm they enforce privileges the certainty of returns – which *prevents* corporations from being able to engage in the entrepreneurship and risk taking necessary to create new products and business opportunities. In other words, normal business and entrepreneurial activities that produce uncertainty are ironically devalued by Wall Street as threatening losses, and are thus seen as deserving of poor credit ratings. Ourousoff concludes that financialization has made it more likely for corporate America to dissemble and subvert its own goals in order to abide by (or resist) the authority of financial analysts.

These ethnographies, and the anthropology of finance, more generally, intersect with the broad set of diverse concerns and questions that informs economic anthropology and the anthropologies of capitalism, money, class, neoliberalism, work, corporations, technology, knowledge, feminism, power and inequality, gender, race, and ethnicity. Moreover, the anthropology of finance also draws from a vast interdisciplinary literature, which includes economic sociology and the sociology of markets, the social studies of finance, and critical management studies. While this compelling subfield has substantively contributed to understanding the 'nuts and bolts' of finance – especially given the methodological (and theoretical) necessity of approaching finance as a local site – the dangers of analytical abstraction still loom large.

Blaming financial abstraction for the ills of contemporary capitalist inequality and change depends on presuming the context and directionality of our social economy, which, I would argue, is contrary to the contributions and strengths of ethnographic specificity. Such arguments, of course, stem in part from longstanding interdisciplinary understandings of capitalism as governed by inevitable, evolutionary, and totalizing logics, demands, and laws – an approach that anthropologists and many social scientists have challenged as well as reproduced. Assuming that finance exhibits these characteristics not only prevents us from examining the particularities and contingencies of finance on the ground, but also reproduces formalistic and dominant ideas about money, markets, society, and morality.

Abstract

Money has been with us since time immemorial. It serves many functions, underwriting exchange and transactions as well as the spatial and temporal integration of human activity. It comes in many forms and is more than a component part of market capitalism. Its modern form is represented by finance, the financial services industry, and what many commentators refer to as the financialization of economy and society. For many writers, modern finance is distinct and autonomous from industries that produce and trade in commodities. But there is little doubt that twenty-first-century globalization would not have been possible without the global financial services industry. Research on the topic is to be found across the social sciences, including accounting, economics, human geography, political science, and sociology. In this article, the geographical building blocks of the global financial services industry are identified, emphasizing the spatial structure of gross flows as well as the role and significance of financial centers. Understanding the geography of finance also requires an appreciation of the various scales, at which finance appears in everyday life. So, for example, the article also focuses upon the relevant literature in geography on financial literacy, financial exclusion, and financial crisis. The article opens and closes with reference to the global financial crisis and, most importantly, the Euro crisis. The Euro crisis has been accompanied by a landscape of despair that is likely to profoundly mark the prospects of whole regions and countries across Europe over the coming decades.

The geography of finance has been a topic of interest for centuries. Shakespeare's plays are replete with commentary on money changers and disreputable posers; some of the most tragic figures in English literature are caught up in financial leverage and obligation. The Globe Theater was just across the River Thames from the public houses and betting shops that were to form the basis of the City of London as the world's most important financial center in the eighteenth century. It remains a vital cog in the global economy, being the switch point for financial assets flowing east to west and north to south on a 24-h, 365-day basis (Clark and Thrift, 2005). Financial centers are more than trading posts. They fuel the real economy, facilitate the trade of commodities and services, and sustain economic growth and development (Wójcik, 2011). If the alchemists of folklore like Merlin the Magician could turn lead into gold, it is all too obvious that the modern alchemists of finance brought the global economy to its knees (Engelen et al., 2012).

It is arguable that money, its functions, and its various physical manifestations have been with us since time immemorial. On the other hand, its institutional structure and significance for society and economy vary over time and space. Some analysts make gross distinctions, comparing the role of money in different regimes of accumulation over enormous stretches of time (feudalism vs. capitalism, etc.). While sympathetic to this logic, too often it imposes a blanket over the subtleties and continuities apparent within and between historical and geographical formations (see Landreth, 2012). So, for instance, it has been argued that the rise of modern financial capitalism over the second half of the twentieth century was accompanied by a profound schism between corporate capitalism and the new institutions that have mobilized financial assets, setting these interests against inherited industry and national formations (Clark, 2000; Walker, 1989). The geography of finance opens up the problematics of finance to scrutiny – taking aim at convention while suggesting that finance can be seen in fresh ways otherwise lost in totalizing conceptions (see Christophers, 2012; Coval and Moskowitz, 2001; compare Merton and Bodie, 2005).

The intellectual foundations of modern financial theory were formalized over the past 50 years: notably Markowitz (1952) on modern portfolio theory, Fama (1970) on the efficient markets hypothesis, and Merton (1990) on modeling risk over time. Those following in their wake developed frameworks for conceptualizing and measuring risk, closing the gap between financial theory and practice with a 'universal' formula for strategy and behavior (as evident in the significance attributed to the Black–Scholes theorem; see MacKenzie, 2006). By the turn of the twenty-first century, it was possible to talk about 'financialization' as a new form of capitalism albeit centered in Anglo-American markets. Whereas it was convenient to suppose that inherited 'varieties of capitalism,' with attendant differences in state–society–economy relations (Hall and Soskice, 2001) would reasonably coexist with one another, financialization was shown to be a threat to persistent difference (Clark and Wójcik, 2007). The euro crisis can be seen as a political response to the power of global financial markets – a test of will between political elites and market sentiment.

In this account of the core themes and issues driving the research program on the geography of finance, we provide a map of finance from the global to the local, from gross flows through to individual decision-making in context. The survey focuses on key elements in the global financial system while providing spatial references for thinking about the forms and functions of finance (Dixon, 2012). By way of conclusion, the survey returns to the euro crisis and its distinctive geography. The role and status of finance in modern societies are highly contested. Nonetheless, understanding the organizing logic of

finance and financial markets has never been so important for the welfare of coming generations.

Global Flows

One way of accounting for the global flows of finance is to map onto commodity trade and exchange; in effect, mapping onto geographical patterns of national and international integration. It is widely observed that trade and exchange among Western developed economies is accompanied by massive financial flows just as low volumes of trade and exchange between developed economies and less developed economies is accompanied by a paucity of financial intermediation and integration (Mishkin, 2006). Even so, periodic resource shortages have tended to enrich the resource-dependent margins of the developed world. The flows of finance accompanying these surges in resource incomes are, however, spatially symmetrical: as the West pays for resources, these payments flow back to Western financial markets for investment.

Global financial integration over the twentieth century can be mapped onto (1) trade and exchange between the UK, its residual empire, and North America, thereafter (2) incorporating Europe and Latin America into systems of exchange, (3) providing Japan and then the newly industrialized Asian economies with a means of financing development, and ultimately (4) placing China at the very center of the global financial system. Each phase of incorporation has benefited the newly industrializing economies, raising living standards and providing financial resources for development. When switching financial assets into the global economy, these assets have been passed through the handful of financial centers that dominate the global financial system. It is not surprising that international trade and development is accompanied by the deepening of domestic financial markets and the mobilization of financial assets through financial centers, national and global.

Whereas commentary on twenty-first-century globalization tends to suggest that financialization has crept into every nook and cranny of the world, we should acknowledge that the global map of finance is highly differentiated. Some countries and some regions are awash with financial assets, while other countries and regions are financially impoverished. Whereas there are huge incentives for financial institutions to seek out opportunities at the margins of the global economy, 'home bias' is a common refrain (Coval and Moskowitz, 1999; Huberman, 2001).

Pricing Tradition

A remarkable feature of Western development since 1970 has been the enormous growth of the financial services industry. Even countries outside the Anglo-American system of financial markets and regulation have experienced high levels of accumulation in financial assets and burgeoning growth in employment in the financial services sector (Wójcik, 2013). Some countries like Germany and the Netherlands, as well as the countries of Scandinavia, are hosts to large financial institutions that have evident global footprints. The classification of national economic systems into 'varieties of capitalism' by reason of their reliance on banks as opposed to markets, corporatism as opposed to the market for corporate governance, and the premium on commodity production and export over financial services, is harder to sustain than is often acknowledged (Clark and Wójcik, 2007). There is considerable evidence that the management of many of Europe's larger companies is very sensitive indeed to the incentives and rewards available in global financial markets (see Bauer et al., 2008). Large corporations are more likely 'global' than 'local' (compare Doremus et al., 1998).

Western countries accumulated vast stores of financial assets through high savings rates whether workplace-based (as in funded pension and retirement schemes) or in individual saving schemes (insurance and otherwise). This is referred to, by some, as the fifth stage of capitalism or pension fund capitalism (Clark, 2000; Clark and Hebb, 2004). Most importantly, the nexus between the production and sale of commodities in local markets and the accumulation and management of financial assets was fractured such that financial institutions became autonomous from commodity-producing industries and sectors. Accompanying this development was the formation of a shared intellectual framework for the management of financial assets, which effectively legitimated the institutional and legal division of responsibilities between the production of savings and the investment of savings (Hawley and Williams, 2000). If a distinctly Anglo-American phenomenon (see La Porta et al., 1998), its boundaries have been systematically extended by the globalization of the financial services industry.

In the space of about 25 years, Western financial markets became drenched in 'surplus' financial assets managed by 'autonomous' financial institutions. The search for premium rates of return in financial markets encourages financial innovation and leverage, which were routinely rewarded (in the short term) even if transitory (in the long term). As markets became more efficient and as transaction costs declined, real rates of return above market performance became harder to find. Whereas opportunities were evident at the margins of the global economy, the transaction costs and the risks incurred by being at the margin were deemed too significant relative to the opportunities for arbitrage in developed financial markets. Indeed, through to the last decade of the twentieth century and the first years of the twenty-first century, it was widely believed that emerging markets lacked the transparency and depth of liquidity needed to sustain large-scale investment programs.

The fact that emerging markets were the source of global financial crises through much of the twentieth century reinforced an unjustified belief in the stability of developed economies' financial markets (Barro, 2006). It was inconceivable that Western financial markets could be 'hosts' to systemic patterns of behavior and institutional irrationalities that would produce a global financial crisis (Clark, 2011).

The Hierarchy of Financial Centers

Why is there a pronounced hierarchy of financial centers? This question can be answered with reference to history, geography, and economics. It is easy enough to explain the contemporary significance of London for Europe and the international financial system by invoking its historical significance as the

switch point for agricultural wealth-seeking opportunities through the Industrial Revolution (at home) and opportunities presented by the expansion of the British Empire (abroad). It is not just history that counts – explaining the resilience of London in relation to its competitors, past and present, is also important (Beaverstock and Hall, 2012). Likewise, it is easy enough to 'explain' London by the fact that it is at the center point in time and space between Asia and North America. If London did not exist, it would have to be invented. Amsterdam, Frankfurt, or Paris could provide the functions that London currently provides given their similar location in time and space. However, economics could also be invoked, referencing the virtues of London as a site for the production of financial services against the alternatives (Faulconbridge et al., 2007).

From a theoretical standpoint, there are three possible answers to the question posed above. Before doing so, it is important to acknowledge a set of economic factors that underpins these explanations. First, collecting, processing, and distributing financial assets on a global basis require enormous investment in the electronic infrastructure of information processing, so much so that just a handful of companies dominate the industry. Second, reinforcing the concentration of the industry is the fact that there are economies of scale in managing and processing financial assets such that just a few providers dominate national financial markets and act as the gateways or portals to the global financial system. Third, notwithstanding commonplace perceptions of a uniform global landscape of financial institutions and markets, there remain persistent differences between nation-states as regards the status attributed to domiciled banks, insurance companies, and related financial institutions. In many cases, nation-states have sought to protect and maintain the national importance of these institutions. They have an interest in mutual survival.

One explanation of the persistence of national and global financial centers has to do with access to information regarding the price of the traded securities, and the formation of expectations about future prices and the risks attending those expectations. At one level, information is virtually free and instantly accessible for market participants, whatever their locations in time and space. Information providers like Bloomberg and Thomson Reuters have transformed the trading desks of financial institutions, providing traders with a panoptic view of national and global financial markets, separately and together. By this account, it would seem that financial markets could easily fall into a single electronic platform floating free of its participants' jurisdictions. Attempts have been made to create such platforms, but ambitions have not been realized. In large part, this is because the electronic processing of publicly available information rarely provides market participants with an edge when seeking to anticipate shifts in market sentiment. In a world of shared information, accessible at a click of a mouse, there is an enormous premium on information gleaned from personal networks and unique vantage points in economic and financial decision-making (Hall and Appleyard, 2008).

A second explanation of the persistence of global financial centers has to do with the importance of market liquidity for investment groups and traders. One reason investors located in national financial centers converge on the relevant macroregional global financial center (such as Tokyo, London, and New York) is that price discovery in national financial centers is often hampered by the limited number of traders and clients. As a consequence, local liquidity may be shallow when compared to the depth of liquidity available in the adjoining global financial center. At the same time, traders located in other national financial centers but overlapping with traders in adjoining financial centers can, in effect, trade through the global center to take advantage of buy-and-sell orders in related stocks across the macroregion. In this manner, liquidity is pooled virtually if not always predictably. What is remarkable about the London market is the diversity of traders by region-of-origin and the buy-and-sell orders they bring with them reflecting very different time horizons, expectations, and desired payoffs. A well-functioning financial center combines liquidity with a diversity of expectations.

A third explanation of the persistence of global financial centers relies upon a quite conventional idea, found in textbooks on economic geography. This explanation rests on a set of basic premises or suppositions: (1) the more specialized a product or service, the larger the market has to be to support provision of that product or service; (2) specialized products and services are, inevitably, linked together in chains of complementary products and services such that provision of one or a small set of these products and services requires the availability of other related products and services; and (3) national and regional financial centers may provide these types of products and services, but are dominated by large financial institutions. In effect, market density is so shallow that there is only space for one provider, thereby limiting the effect of market competition on the nature, cost, and value of these products and services. Global financial centers have both the requisite range of products and services, and the requisite density of skilled market participants consistent with competition for the provision of those products and services (Faulconbridge, 2008).

By this account, London's place in the global financial system is underwritten by the infrastructure supporting the depth and scope of market information, liquidity, and the diversity of expectations. Reinforcing these advantages is the density of London-based intermediaries competing for mandates. Not surprisingly, financial institutions, not domiciled in these types of centers often leapfrog regional and national financial centers to gain access to the most important global markets for financial securities, products, and services. Leapfrogging has been made a more effective strategy over the past 20 years by the development of formal information channels, which have facilitated access to markets on a virtually instantaneous basis, if not always in the real-time flux and flow of changing expectations. In this context, there is also an intimate and thoroughly reinforcing relationship between London and off-shore financial centers (Wainwright, 2011).

Regional Growth and Development

There is, quite obviously, extraordinary interest in the structure and performance of financial markets, not least their coordination over time and space. However, care should be taken not to ignore other salient issues, including the significance of

financial innovation for economic growth and development. In a series of papers, King and Levine (1993a, 1993b) showed that developing countries' economic growth is, in the first instance, dependent upon the robustness of systems of exchange and transaction, including the availability of money that serves as a recognized and reliable store of value. They also show that economic development is accompanied by increasing financial sophistication when trade and exchange become a viable mechanism for accumulating surplus value. They do suggest, however, that financial sophistication can, at some point in the development pathway, outstrip the demand for financial products and services. Just as some countries may be hamstrung by the Dutch disease (resource wealth), others that specialize in financial products and services may find that other sectors are crowded out in the national economy.

Importantly, financial intermediation has played a major role in facilitating the growth and development of subnational regions of innovation such as Silicon Valley and Rt128/495 Boston, the Oxford–London–Cambridge complex, and the Third Italy (Babcock-Lumish, 2005). It would be misleading to suggest that these regions of innovation have relied upon the same types of financial institutions to fuel new start-ups, the investment in ideas, and the realization of value. Further, regions of innovation have faltered or failed to take off when they are unable to access investors knowledgeable about the innovation process and the different types of financing needed to transform an idea into a marketable product (Backher et al., 2014). Some regions rely upon dispersed and uncoordinated small investors, whereas other regions rely upon venture capital firms that are large enough to mobilize investors across the world through portfolios of investment opportunities. Other regions rely upon banking institutions and their lending practices, sustained by long-term relationships governed by trust rather than contract. In still other cases, intermediation is highly formalized and often remote from local conditions.

At the other end of the spectrum, large multinational companies rely upon a combination of internal financial resources and external investors to sustain their businesses. While notionally domiciled in a specific country, with related firms managed and reporting through to the global headquarters of these companies, the evidence suggests that these types of companies have become quite responsive to global investors (Bauer et al., 2008). In many cases, these types of companies carry many hundreds of investors from across the world. Few of these investors have the size or the significance necessitating 'active management'; in fact, these types of companies deliberately dampen the power of shareholders by cross-listing in other jurisdictions so as to attract investors who have neither the interest nor the capacity to organize themselves into voting coalitions. One or two steps removed from their host countries' governance procedures and rules and regulations, these types of companies have used the relative anonymity of global financial markets to shield themselves from intervention.

Nonetheless, financial institutions like pension funds and investment managers have become more active in holding large corporations to account, even if governments of their home jurisdictions are reluctant to affect the powers of their national champions. In some cases, these financial institutions have sought to 'name and shame' corporate executives, thereby demonstrating that reputation must be earned, not assumed. This occurs when institutions mount campaigns at annual general meetings to influence corporate governance policies as well as global and local environmental and social standards. Out of the limelight, financial institutions have also sought to engage with senior executives to affect corporate management on issues such as reputation, license to operate, and long-term sustainability. For some, such issues are rather ephemeral, given the map of corporate power. However, these issues are increasingly on the agenda for governments of advanced economies seeking to ensure the long-term success of their leading corporations.

Mapping Financial Literacy

By this account, the map of global finance is a map of financial stocks and flows mediated by institutions and markets. In play is the structure and performance of financial institutions and related markets – if we have the power to redesign and regulate the system. At another level, however, financial institutions and markets provide an action space for individuals and communities seeking to realize their own aspirations in terms of personal and collective welfare. Put slightly differently, financial institutions and markets can be treated as the 'environment' in which decisions are taken and plans are made about the future. Obviously, this environment can be characterized in various ways, including whether it is benign, poor in resources like knowledge and information, or rich in these resources (Leyshon and French, 2008). Since financial markets are subject to a risk and uncertainty, this may harm those who must rely upon institutions and markets for their own prospects and the prospects of others.

It is arguable that these issues have become more important over the past couple of decades than hitherto acknowledged (Leyshon and Thrift, 1997). For some, the increasing need for individuals to plan for the future in the context of financial risk and uncertainty reflects the hegemony of neoliberalism (the discounting of nation-state capacity, the increasing role of markets in pricing inherited traditions, and the advent of globalization; see Langley, 2008). Whether neoliberalism is a systematic political project or the artifact of juxtaposed and overlapping forces is subject to debate. It is apparent, however, that the past certainties associated with Anglo-American liberal capitalism, welfare states, and European social democracies have been systematically discounted over the past 25 years. This is especially obvious in areas of social policy such as pension and retirement benefits, the provision of health care, and the provision and pricing of higher education. It would be misleading to suggest that these trends are everywhere the same; European pension reform takes many shapes and sizes. None represent an accepted model to which nation-states are converging (Clark, 2003).

By convention, it is assumed that consumers bear the risks of their decisions. However, as the nature and scope of the decisions to be made have changed and the long-term consequences of making poor decisions have become apparent, the doctrine of *caveat emptor* has been subject to searching criticism and analysis. At one level, it is apparent that the market for financial products and services is not nearly as competitive as

theorists suppose, leading, in some instances, to the systematic discounting of individual and collective welfare. Here, the vulnerability of consumers of financial products can be explained by persistent information asymmetries, which shelter providers deploying the so-called sharp practices. The vulnerability of consumers can also be explained by the complex nature of financial products, which nonetheless seem to promise an entirely obvious result: a liveable retirement income. The evidence suggests that certain segments of the population, particularly in certain regions and city neighborhoods, are more vulnerable than others to 'mis-selling' (Leyshon et al., 2004, 2006).

The average consumer is bound to struggle when attempting to understand the possible consequences associated with certain types of financial products. For some, the issue is simply one of a lack of knowledge and understanding of finance (in general) and the products and services (in particular) that require domain-specific judgment and experience. For others, more confident in their ability and the scope of their experience, there remain pitfalls for the unwary. It was not uncommon through much of the 1990s for the professional classes of southern England to sign up to endowment mortgages, invest in with-profit insurance contracts, and take on interest-only mortgages for buy-to-let housing in some of the less fashionable districts of London. Each type of product carries with it considerable risks and uncertainties. Together these products represent a profound threat to the solvency of households that unknowingly carry highly correlated downside financial risks. Not surprisingly, both the global financial crisis and the euro crisis revealed that many households had assumed a level of financial leverage antithetical to their long-term interests.

One response to the costs associated with poor individual financial decision-making has been to improve the quality and quantity of information that vendors must make available when offering financial products for sale. Governments have established all kinds of information portals, as well as internet-based decision cues and decision trees that may prompt better, if not entirely optimal, decision-making. Public uptake of these advisory services has been limited and largely ignored by those who could benefit the most from their use. Governments have also sought to better understand the nature and scope of financial literacy in the community, paying particular attention to systematic trends by sociodemographic characteristics and geographical reference points. It has been shown that financial literacy is systematically distributed throughout the community with troubling implications for long-term income inequality and well-being. Here, again, government programs have been launched to 'improve' financial literacy especially among secondary school students who, it is assumed, would carry this training with them throughout their lives.

Most importantly, it is apparent that there are maps of financial literacy within countries and between their regions, just as there are significant differences between countries in their levels of financial literacy. Accounting for these maps of financial literacy is of considerable importance to academics, policymakers, and even multilateral organizations (Clark, 2013, 2014a). However, it has been recognized that the testing regimes upon which surveys of financial literacy are based often contain questions on financial concepts that, for many people, may appear rather abstract and lacking in saliency. Equally troubling, it is not always obvious that the supposed 'correct' answers to questions that seek to represent the foundations of financial literacy are unambiguous or even plausible to people in specific situations (time and space). That is, the testing regime underpinning the financial literacy project may not be as relevant as assumed nor indicative of the decision competencies of people given their particular circumstances.

Future Research

Much of the literature on the geography of finance is about institutions and markets and the tensions between local, national, and global imperatives. As such, this literature overlaps with and intersects with related work in political science on 'varieties of capitalism.' Recall that this school of thought has focused on the formal or institutional differences between countries, even blocks of countries, so as to explain how and why the imperatives of global finance may not prompt convergence upon one model of capitalism (Hall and Soskice, 2001). One criticism of this approach is that, for 'difference' to carry sufficient weight so as to counter the imperatives of global finance, nation-states are treated as organic wholes impervious to the attractions of financial rewards internal and external to these economies. Empirical evidence suggests that national models may fracture internally as those that benefit from financial markets bypass local custom and convention (Clark and Wójcik, 2007).

Related criticism, launched by Dixon (2012), is that explanations of persistent differences between countries in the face of global financial imperatives rely upon differences in the formal and informal institutions of nation-states. In effect, form is assumed determinant of function in that the latter can be read off the former. However, this type of analytical logic often misses the fact that institutional form is more malleable than many believe, being responsive to changes in the external environment on an incremental basis if not always on a structural basis. More often than not, those that hold fast to the difference thesis must look back in history for distinctive differences between nation-states and their associated regimes of accumulation. Part and parcel of this strategy of idealization is the discounting of current developments and apparent changes in institutional performance. This is not to say that global finance is hegemonic. But it does suggest that economic and political institutions may be forced to accommodate the imperatives of global finance (Dixon, 2014).

This issue is being played out in Europe via the euro crisis. Simply stated, the euro crisis pits the commitment of Eurozone members to an idealized conception of the European community against the expectations of global financial institutions. However imperfect the Eurozone is in terms of its structure, composition, and governance, Germany has led a coalition of the faithful in an attempt to stare down bond traders who believe that the Eurozone is not functionally viable in its current form. In part, this has involved holding to ransom countries such as Greece, Spain, and Portugal in the Eurozone as a calculated gesture of defiance, which implicitly signals that Europe is willing to bear the price of solidarity. Yet, the price of solidarity is unevenly distributed: throughout Europe, many young people face high and increasing rates of unemployment

and the prospect of long-term impoverishment. Throughout Europe, low or negative rates of economic growth are accompanied by decreasing real incomes with long-term implications for those who rely upon waged work for their well-being. Furthermore, there seems no way out for the residents of Greece, Spain, and Portugal (and perhaps southern Italy). These countries are experiencing economic depressions at least as significant as the Great Depressions of the 1890s and 1930s. Political extremism is on the horizon.

Is the price of maintaining this idealized community worth paying? Given the obvious and quite profound shortcomings in the design and construction of the Eurozone, is the price of European solidarity legitimate? At present, these questions are answered in the affirmative – at least by the political leaders of the dominant Eurozone countries. However, instead of seeing the issue through the eyes of Europe's political leaders, a worthy project that could join many social science disciplines, especially human geography with economic geography, would be to study the emerging map of European unemployment, poverty, and social crisis. As indicated above, this map is likely to spread across Europe and to be increasingly differentiated in terms of those regions that demonstrate resilience in the face of this disaster and those regions – even whole countries – that simply fail under the weight of history (Clark, 2014b).
